Lecture 5
Minimum cost flow models and algorithms

Ann-Brith Strömberg

2010-03-25

Maximum flow models

- ▶ Consider a district heating network with pipelines that transports energy from a number of sources to a number of destinations
- ▶ The network has several branches and intersections
- ▶ Pipe segment (i,j) has a maximum capacity of K_{ij} units of flow per time unit
- ▶ A pipe can be one- or bidirectional
- ▶ What is the maximum total amount of flow per time unit through this network?
- ▶ Another application of maximum flow models is evacuation of buildings

Linear programming formulation of maximum flow problem

- ▶ Graph: $G = (V, A, K)$ (nodes, directed arcs, arc capacities)

$$\begin{aligned} \text{[Primal]} \quad & \max && v, \\ & \text{s.t.} && - \sum_{j:(s,j) \in A} x_{sj} + v = 0, \\ & && \sum_{j:(j,t) \in A} x_{jt} - v = 0, \\ & && \sum_{i:(i,k) \in A} x_{ik} - \sum_{j:(k,j) \in A} x_{kj} = 0, \quad k \in V \setminus \{s, t\} \\ & && x_{ij} \leq K_{ij}, \quad (i, j) \in A \\ & && x_{ij} \geq 0, \quad (i, j) \in A \end{aligned}$$

$$\begin{aligned} \text{[Dual]} \quad & \min && \sum_{(i,j) \in A} K_{ij} \gamma_{ij}, \\ & \text{s.t.} && -\pi_i + \pi_j + \gamma_{ij} \geq 0, \quad (i, j) \in A \\ & && \pi_s - \pi_t \geq 1, \\ & && \gamma_{ij} \geq 0, \quad (i, j) \in A \end{aligned}$$

Minimum cut

- ▶ A *cut* is a set of arcs which, when deleted, interrupt all flow in the network between the source s and the sink t
- ▶ The *cut capacity* equals the sum of capacities on all the arcs through the cut
- ▶ Finding the minimum cut is equal to solve the dual of the max flow problem
- ▶ Theorem: value of maximum flow = value of minimum cut (strong duality)

Transportation models: An example

- ▶ MG Auto has three plants, LA, Detroit, New Orleans, and two distribution centers, Denver and Miami
- ▶ Capacities of the plants: 1000, 1500, and 1200 cars
- ▶ Demands at distributions centers: 2300 and 1400 cars
- ▶ Transportation cost per car between plants and centers:

	Denver	Miami
LA	\$80	\$215
Detroit	\$100	\$108
New Orleans	\$102	\$68

- ▶ Find the cheapest shipping schedule to satisfy the demand

Linear programming formulation of MG Auto

- ▶ Variables: x_{ij} = number of cars sent from plant i to distribution center j

$$\min z = 80x_{11} + 215x_{12} + 100x_{21} + 108x_{22} + 102x_{31} + 68x_{32}$$

$$\begin{aligned} \text{s.t.} \quad & x_{11} + x_{12} && = 1000 && (\text{LA}) \\ & & x_{21} + x_{22} && = 1500 && (\text{Detr}) \\ & & & x_{31} + x_{32} &= 1200 && (\text{NO}) \\ & x_{11} & & + x_{21} & & + x_{31} &= 2300 && (\text{Den}) \\ & & x_{12} & & + x_{22} & & + x_{32} &= 1400 && (\text{Mi}) \\ & x_{11}, & x_{12}, & x_{21}, & x_{22}, & x_{31}, & x_{32} &\geq 0 \end{aligned}$$

Definition of the transportation model

- ▶ m sources and n destinations \Leftrightarrow **nodes**
- ▶ a_i = amount of supply at source (node) i
- ▶ b_j = amount of demand at destination (node) j
- ▶ **Arc** (i, j) \Leftrightarrow connection from source i to destination j
- ▶ c_{ij} = cost per unit of flow on arc (i, j)
- ▶ **Variables:** x_{ij} = amount of goods shipped on arc (i, j)
- ▶ **Objective:** find $x_{ij} \geq 0$ such that the total cost is minimized while satisfying all supply and demand restrictions

Linear programming transportation model

$$\min z := \sum_{i=1}^m \sum_{j=1}^n c_{ij} x_{ij}$$

$$\text{s.t.} \quad \sum_{j=1}^n x_{ij} \leq a_i, \quad i = 1, \dots, m \quad (\text{supply})$$

$$\sum_{i=1}^m x_{ij} \geq b_j, \quad j = 1, \dots, n \quad (\text{demand})$$

$$x_{ij} \geq 0, \quad i = 1, \dots, m, \quad j = 1, \dots, n$$

- ▶ Feasible solutions exist *if and only if* $\boxed{\sum_i a_i \geq \sum_j b_j}$
- ▶ The constraint matrix has special properties (totally unimodular) \Rightarrow integer solutions in extreme points of the feasible polyhedron
- ▶ This property holds for all problems that can be formulated as linear flows in networks

A balanced transportation model

- ▶ What if total amount of demand \neq total amount of supply?
($\sum_i a_i > \sum_j b_j$ (feasible) or $\sum_i a_i < \sum_j b_j$ (infeasible))

$$\begin{array}{ll} \min z := & \sum_{i=1}^m \sum_{j=1}^n c_{ij} x_{ij} \\ \text{s.t.} & \sum_{j=1}^n x_{ij} \leq a_i, \quad i = 1, \dots, m \\ & \sum_{i=1}^m x_{ij} \geq b_j, \quad j = 1, \dots, n \\ & x_{ij} \geq 0, \quad i = 1, \dots, m, j = 1, \dots, n \end{array}$$

⇒ **Balance** the model by dummy source ($m + 1$) or destination ($n + 1$)

- ▶ Suppose $\sum_i a_i > \sum_j b_j \Rightarrow$ Let $b_{n+1} := \sum_{i=1}^m a_i - \sum_{j=1}^n b_j$

⇒ **Balanced** transportation model—equality constraints

$$\begin{array}{ll} \min z := & \sum_{i=1}^m \sum_{j=1}^{n+1} c_{ij} x_{ij} \\ \text{s.t.} & \sum_{j=1}^{n+1} x_{ij} = a_i, \quad i = 1, \dots, m \\ & \sum_{i=1}^m x_{ij} = b_j, \quad j = 1, \dots, n + 1 \\ & x_{ij} \geq 0, \quad i=1, \dots, m, j=1, \dots, n+1 \end{array}$$

General network flow problems

- ▶ A network consist of a set N of *nodes* linked by a set A of *arcs*
- ▶ A distance/cost c_{ij} is associated with each arc
- ▶ Each node i in the network has a net demand d_i
- ▶ Each arc has an (unknown) amount of flow x_{ij} that is restricted by a maximum capacity $u_{ij} \in [0, \infty]$ and a minimum capacity $\ell_{ij} \in [0, u_{ij}]$
- ▶ The flow through each node must be *balanced*
- ▶ A network flow problem can be formulated as a linear program
- ▶ All extreme points of the feasible set are *integral* – due to the *unimodularity* property of the constraint matrix (see Ch. 8.6.3)

Minimum cost flow in a general network: An example

- ▶ Two paper mills: Holmsund and Tuna
- ▶ Three saw mills: Silje, Graninge and Lunden
- ▶ Two storage terminals: Norrstig and Mellansel

Facility	Supply (m^3)	Demand (m^3)
Silje	2400	
Graninge	1800	
Lunden	1400	
Holmsund		3500
Tuna		2100

Minimum cost flow in a general network: An example

- ▶ Transportation opportunities:

From	To	Price/m ³	Capacity (m ³)
Silje	Norrstig	20	900
Silje	Mellansel	26	1000
Silje	Holmsund	45	1100
Graninge	Norrstig	8	700
Graninge	Mellansel	14	900
Graninge	Holmsund	37	600
Graninge	Tuna	22	600
Lunden	Mellansel	32	600
Lunden	Tuna	23	1000
Norrstig	Holmsund	11	1800
Norrstig	Mellansel	9	1800
Mellansel	Norrstig	9	1800
Mellansel	Tuna	9	1800

Minimum cost flow in a general network: An example

- ▶ Objective: Minimize transportation costs
- ▶ Satisfy demand
- ▶ Do not exceed the supply
- ▶ Do not exceed the transportation capacities
- ▶ An optimal solution

Minimum cost flow in a general network: An example

$$\begin{aligned}
 \min z := & 20x_{SN} + 26x_{SM} + 45x_{SH} + 8x_{GN} + 14x_{GM} \\
 & + 37x_{GH} + 22x_{GT} + 32x_{LM} + 23x_{LT} + 11x_{NH} \\
 & + 9x_{NM} + 9x_{MN} + 9x_{MT} \\
 \text{subject to} & \quad -x_{SN} - x_{SM} - x_{SH} = -2400 \quad (\text{Silje}) \\
 & \quad -x_{GN} - x_{GM} - x_{GH} - x_{GT} = -1800 \quad (\text{Granninge}) \\
 & \quad -x_{LM} - x_{LT} = -1400 \quad (\text{Lunden}) \\
 & \quad x_{SN} + x_{GN} + x_{MN} - x_{NM} - x_{NH} = 0 \quad (\text{Norrstig}) \\
 & \quad x_{SM} + x_{LM} + x_{GM} + x_{NM} - x_{MN} - x_{MT} = 0 \quad (\text{Mellansel}) \\
 & \quad x_{SH} + x_{GH} + x_{NH} = 3500 \quad (\text{Holmsund}) \\
 & \quad x_{GT} + x_{LT} + x_{MT} = 2100 \quad (\text{Tuna}) \\
 & \quad 0 \leq x_{SN} \leq 900 \\
 & \quad 0 \leq x_{SM} \leq 1000 \\
 & \quad 0 \leq x_{SH} \leq 1100 \\
 & \quad 0 \leq x_{GN} \leq 700 \\
 & \quad 0 \leq x_{GM} \leq 900 \\
 & \quad 0 \leq x_{GH} \leq 600 \\
 & \quad 0 \leq x_{GT} \leq 600 \\
 & \quad 0 \leq x_{LM} \leq 600 \\
 & \quad 0 \leq x_{LT} \leq 1000 \\
 & \quad 0 \leq x_{NH} \leq 1800 \\
 & \quad 0 \leq x_{NM} \leq 1800 \\
 & \quad 0 \leq x_{MN} \leq 1800 \\
 & \quad 0 \leq x_{MT} \leq 1800
 \end{aligned}$$

- ▶ The columns \mathbf{A}_j of the equality constraint matrix ($\mathbf{Ax} = \mathbf{b}$) have one 1-element, one -1 -element; the remaining elements are 0

Minimum cost flow in a general network: LP formulation

- ▶ $G = (N, A)$ is a network with nodes N and arcs A , $|N| = n$
- ▶ x_{ij} is the amount of flow on the arc from node i to node j ,
- ▶ l_{ij} and u_{ij} are lower and upper limits for the flow on arc (i, j) ,
- ▶ c_{ij} is the cost per unit of flow on arc (i, j) , and
- ▶ d_i is the demand in node i

$$\begin{aligned} \min \quad & \sum_{(i,j) \in A} c_{ij} x_{ij}, \\ \text{s.t.} \quad & \sum_{i:(i,k) \in A} x_{ik} - \sum_{j:(k,j) \in A} x_{kj} = d_k, \quad k \in N, \\ & l_{ij} \leq x_{ij} \leq u_{ij}, \quad (i,j) \in A. \end{aligned}$$

Linear programming dual:

$$\begin{aligned} \max \quad & \sum_{k \in N} d_k y_k + \sum_{(i,j) \in A} (l_{ij} \alpha_{ij} - u_{ij} \beta_{ij}), \\ \text{s.t.} \quad & y_j - y_i + \alpha_{ij} - \beta_{ij} = c_{ij}, \quad (i,j) \in A, \\ & \alpha_{ij}, \beta_{ij} \geq 0, \quad (i,j) \in A. \end{aligned}$$

The simplex method for minimum cost flow in a general network

- ▶ A solution is optimal if
 - ▶ the primal and dual solutions are feasible and
 - ▶ the complementary conditions are fulfilled
- ▶ Reduced cost: $\bar{c}_{ij} = c_{ij} + y_i - y_j$
- ▶ Complementary conditions, $(i, j) \in A$
 - ▶ $\alpha_{ij}(x_{ij} - \ell_{ij}) = 0$
 - ▶ $\beta_{ij}(u_{ij} - x_{ij}) = 0$
 - ▶ $x_{ij}(\bar{c}_{ij} - \alpha_{ij} + \beta_{ij}) = 0$
- ▶ Assume that $\ell_{ij} < u_{ij}$.
- ▶ A feasible solution x_{ij} , $(i, j) \in A$, is optimal if the following hold
 - ▶ $x_{ij} = u_{ij} \Rightarrow \alpha_{ij} = 0 \Rightarrow$ Reduced cost: $\bar{c}_{ij} = -\beta_{ij} \leq 0$
 - ▶ $x_{ij} = \ell_{ij} \Rightarrow \beta_{ij} = 0 \Rightarrow$ Reduced cost: $\bar{c}_{ij} = \alpha_{ij} \geq 0$
 - ▶ $\ell_{ij} < x_{ij} < u_{ij} \Rightarrow \alpha_{ij} = \beta_{ij} = 0 \Rightarrow$ Reduced cost: $\bar{c}_{ij} = 0$

The Simplex algorithm for general minimum cost flows

- ▶ The arc (i, j) correspond to the variable x_{ij} , $(i, j) \in A$
- ▶ A *basic solution* is characterized by the following;
 - ▶ If $\ell_{ij} < x_{ij} < u_{ij} \Rightarrow$ the arc (i, j) is in the *basis*
 $\Leftrightarrow x_{ij}$ is a basic variable
 - ▶ If $x_{ij} = \ell_{ij}$ or $x_{ij} = u_{ij} \Rightarrow$ the arc (i, j) *may* be in the *basis*
 $\Leftrightarrow x_{ij}$ *may* be a basic variable
 - ▶ There are exactly $n - 1$ basic arcs which form a *spanning tree* in G (one primal equation is a linear combination of the rest and can thus be removed)

The Simplex algorithm for minimum cost flows (Ch. 8.7)

1. Find a feasible solution (a spanning tree of basic arcs)
2. Compute reduced costs $\bar{c}_{ij} = c_{ij} + y_i - y_j$ for all non-basic arcs
3. Check termination criteria: If for every arc (i, j)
 - ▶ either: $\bar{c}_{ij} = 0$ and $\ell_{ij} \leq x_{ij} \leq u_{ij}$,
 - ▶ or: $\bar{c}_{ij} < 0$ and $x_{ij} = u_{ij}$,
 - ▶ or: $\bar{c}_{ij} > 0$ and $x_{ij} = \ell_{ij}$

hold, then STOP. x_{ij} , $(i, j) \in A$ is an optimal solution

4. *Entering variable (arc)*: $(p, q) \in \arg \max_{(i,j) \in I} |\bar{c}_{ij}|$
 $I =$ the set of non-basic arcs *not* fulfilling the conditions in 3.
5. *Leaving variable (arc)*: Send flow along the cycle defined by the current *basis* (spanning tree) and the arc (p, q) . The arc (i, j) whose flow x_{ij} first reaches u_{ij} or ℓ_{ij} leaves the basis.
6. Go to step 2

The assignment model (Ch. 13.5)

- ▶ A special case of the network flow model (and of the transportation model)
- ▶ Given n persons and n jobs
- ▶ Given further the cost c_{ij} of assigning person i to job j
- ▶ Binary variables $x_{ij} = 1$ if person i does job j and $x_{ij} = 0$ otherwise
- ▶ Find the cheapest assignment of persons to jobs such that all jobs are done

$$\begin{array}{ll} \min & \sum_{ij} c_{ij} x_{ij} \\ \text{s.t.} & \sum_j x_{ij} = 1 \quad \forall i \\ & \sum_i x_{ij} = 1 \quad \forall j \\ & x_{ij} \geq 0 \quad \forall i, j \end{array}$$

- ▶ The optimal solution is binary (due to the totally unimodular constraint matrix)

An assignment example

- ▶ 3 children: John, Karin and Tina
- ▶ 3 tasks: mow, paint and wash.
- ▶ Given further a “cost” (time, uncomfort,...) for each combination of child/task
- ▶ How should the parents distribute the tasks to minimize the cost?

	Mow	Paint	Wash
John	15	10	9
Karin	9	15	10
Tina	10	12	8

- ▶ Choose exactly one element in each row and one in each column
