Lecture 7 Linear and integer optimization with applications

• Relaxations: cutting planes and Lagrangean duals

• TSP and routing problems

• Branch-and-bound for structured problems

## Good and ideal formulations

## Cutting planes: A very small example

#### Consider the following ILP:

 $\min\{-x_1 - x_2 : 2x_1 + 4x_2 \le 7, x_1, x_2 \ge 0 \text{ and integer}\}\$ 

• ILP optimal solution: z = -3,  $\mathbf{x} = (3, 0)$ 

• LP (continuous relaxation) optimum: z = -3.5,  $\mathbf{x} = (3.5, 0)$ 

# Generate a simple cut "Divide the constraint" by 2 and round the RHS down $x_1 + 2x_2 \le 3.5 \Rightarrow x_1 + 2x_2 \le 3$ Adding this cut to the continuous relaxation yields the optimal ILP solution

## Cutting planes: valid inequalities

(Ch. 14.4)

#### Consider the ILP

- LP optimum: z = 66.5,  $\mathbf{x} = (4.5, 3.5)$
- ILP optimum: z = 58, **x** = (4,3)

#### Generate a VI:

"Add" the two constraints (1) and (2):  $6x_1 + 4x_2 \le 41 \Rightarrow$  $3x_1 + 2x_2 \le 20 \Rightarrow \mathbf{x} = (4.36, 3.45)$ 

#### Generate another VI:

$$\begin{array}{l} "7 \cdot (1) + (2)" \colon 22x_2 \leq 77 \Rightarrow x_2 \leq 3 \\ \Rightarrow \mathbf{x} = (4.57, 3) \end{array}$$

# Cutting plane algorithms (iterativley better approximations of the convex hull) (Ch. 14.5)

• Choose a suitable mathematical formulation of the problem

#### A general cutting plane algorithm

- Solve the linear programming (LP) relaxation
- If the solution is integer, STOP. An optimal solution is found
- Add one or several valid inequalities that cut off the fractional solution but none of the integer solutions
- Sesolve the new problem and go to step 2.

• *Remark:* An inequality in higher dimensions defines a *hyper-plane*; therefore the name cutting *plane* 

## About cutting plane algorithms

- Problem: It may be necessary to generate VERY MANY cuts
- Each cut should also pass through at least one integer point ⇒ faster convergence
- Methods for generating valid inequalities
  - Chvatal-Gomory cuts (combine constraints, make beneficial roundings of LHS and RHS)
  - Gomory's method: generate cuts from an optimal simplex basis (Ch. 14.5.1)
- Pure cutting plane algorithms are usually less efficient than branch–&–bound
- In commercial solvers (e.g. CPLEX), cuts are used to help (presolve) the branch-&-bound algorithm
- For problems with specific structures (e.g. TSP and set covering) problem specific classes of cuts are used

# Lagrangian relaxation ( $\Rightarrow$ optimistic estimates of $z^*$ ) (Ch. 17.1–17.2)

Consider a minimization integer linear program (ILP)

Assume that the constraints (1) are complicating (subtour eliminating constraints for TSP, e.g.)

- Define the set  $X = \{ \mathbf{x} \in Z_+^n \, | \, \mathbf{D} \mathbf{x} \le \mathbf{d} \}$
- Remove the constraints (1) and add them—with penalty parameters **v**—to the objective function

$$h(\mathbf{v}) = \min_{\mathbf{x} \in X} \left\{ \mathbf{c}^{\mathrm{T}} \mathbf{x} + \mathbf{v}^{\mathrm{T}} (\mathbf{A} \mathbf{x} - \mathbf{b}) \right\}$$
(3)

## Weak duality of Lagrangian relaxations

#### Theorem

For any 
$$\mathbf{v} \geq \mathbf{0}$$
 it holds that  $h(\mathbf{v}) \leq z^*$ .

#### Bevis.

Let  $\overline{\mathbf{x}}$  be feasible in [ILP]  $\Rightarrow \overline{\mathbf{x}} \in X$  and  $\mathbf{A}\overline{\mathbf{x}} \leq \mathbf{b}$ . It then holds that

$$h(\mathbf{v}) = \min_{\mathbf{x} \in X} \left\{ \mathbf{c}^{\mathrm{T}} \mathbf{x} + \mathbf{v}^{\mathrm{T}} (\mathbf{A} \mathbf{x} - \mathbf{b}) 
ight\} \le \mathbf{c}^{\mathrm{T}} \overline{\mathbf{x}} + \mathbf{v}^{\mathrm{T}} (\mathbf{A} \overline{\mathbf{x}} - \mathbf{b}) \le \mathbf{c}^{\mathrm{T}} \overline{\mathbf{x}}.$$

Since an optimal solution  $\mathbf{x}^*$  to [ILP] is also feasible, it holds that  $h(\mathbf{v}) \leq \mathbf{c}^T \mathbf{x}^* = z^*$ .

 $\Rightarrow$   $h(\mathbf{v})$  is a *lower bound* on the optimal value  $z^*$  for any  $\mathbf{v} \geq \mathbf{0}$ 

The best lower bound is given by

$$h^* = \max_{\mathbf{v} \ge \mathbf{0}} h(\mathbf{v}) = \max_{\mathbf{v} \ge \mathbf{0}} \left\{ \min_{\mathbf{x} \in X} \left\{ \mathbf{c}^{\mathrm{T}} \mathbf{x} + \mathbf{v}^{\mathrm{T}} (\mathbf{A} \mathbf{x} - \mathbf{b}) 
ight\} 
ight\} \le z^*$$

## Tractable Lagrangian relaxations

- Special algorithms for minimizing the Lagrangian dual function *h* exist (e.g., subgradient optimization, Ch. 17.3)
- *h* is always concave but typically nondifferentiable
- For each value of  $\mathbf{v}$  chosen, a subproblem (3) must be solved
- For general ILP's: typically a non-zero duality gap  $h^* < z^*$
- The Lagrangian relaxation bound is never worse that the linear programming relaxation bound, i.e.  $z^{\text{LP}} \leq h^* \leq z^*$
- If the set X has the integrality property (i.e.,  $X^{\text{LP}}$  has integral extreme points) then  $h^* = z^{\text{LP}}$
- Choose the constraints (Ax ≤ b) to dualize such that the relaxed problem (3) is computationally tractable but still does not possess the integrality property

#### [HOMEWORK]

Find optimistic and pessimistic bounds for the following ILP example using the branch–&–bound algorithm, a cutting plane algorithm, and Lagrangean relaxation.

The linear programming optimal solution is given by z = 23.75,  $x_1 = 3.75$  and  $x_2 = 1.25$ 

## The assignment model

# (Ch. 13.5)

Assign each task to one resource, and each resource to one task

• Linear cost  $c_{ij}$  for assigning task i to resource j,  $i, j \in \{1, \ldots, n\}$ 

 $\sum$ 

 $\overline{i=1}$ 

• Variables:  $x_{ij} = \begin{cases} 1, & \text{if task } i \text{ is assigned to resource } j \\ 0, & \text{otherwise} \end{cases}$ 

#### The mathematical model

min

subject to

$$\sum_{i=1}^{n} c_{ij} x_{ij}$$

$$\sum_{j=1}^{n} x_{ij} = 1, \quad i = 1, \dots, n$$

$$\sum_{i=1}^{n} x_{ij} = 1, \quad j = 1, \dots, n$$

$$x_{ij} > 0, \quad i, j = 1, \dots, n$$

Lecture 7

Linear and integer optimization with applications

## The assignment model

#### Choose one element from each row and each column

- This integer linear model has integral extreme points, since it can be formulated as a network flow problem (Ch. 8) which has a unimodular constraint matrix (Def. 8.1)
- Can be efficiently solved using, e.g., the network simplex algorithm
- More efficient special purpose (primal-dual-graph-based) algorithms exist

## The travelling salesperson problem

# (TSP, Ch. 13.10)

- Given *n* cities and connections between all cities (distances on each connection)
- Find the shortest tour that passes through all the cities

• Complexity: NP-hard due to the combinatorial explosion

## An ILP formulation of the TSP problem

- Let the distance from city *i* to city *j* be *d<sub>ij</sub>*
- Introduce binary variables x<sub>ij</sub> for each connection
- Let  $V = \{1, ..., n\}$  denote the set of nodes (cities)

$$\begin{array}{rcl} \min & \sum_{i \in V} \sum_{j \in V} d_{ij} x_{ij}, & (0) \\ \text{s.t.} & \sum_{j \in V} x_{ij} &= 1, & i \in V, & (1) \\ & \sum_{i \in V} x_{ij} &= 1, & j \in V, & (2) \\ & \sum_{i \in U, j \in V \setminus U} x_{ij} &\geq 1, & \forall U \subset V : 2 \leq |U| \leq |V| - 2, & (3) \\ & x_{ij} &\in \{0, 1\}, & i, j \in V & (4) \end{array}$$

- Cf. the assignment problem
- Enter and leave each city exactly once  $\Leftrightarrow$  (1) and (2)
- Constraints (3): subtour elimination

## Solution methods for the TSP Problem

- Tailored branch-&-bound (Ch. 15)
- Heuristics
  - Constructive heuristics (Ch. 16.3)
  - Local search heuristics (Ch. 16.4)
  - Approximation algorithms (Ch. 16.6)
  - Metaheuristics (Ch. 16.5)
- ...
- Common difficulty for all solution methods for the TSP: Combinatorial explosion: # possible tours  $\approx n!$
- $\Rightarrow$  Very many subtour elimination constraints (3)

## Branch-and-bound algorithm for TSP

- Relaxing just the binary constraints (4) in TSP does not yield a tractable problem, since the number of subtour elinimating constraints (3) is very large
- $\Rightarrow$  An LP with very many constraints
  - Relaxing the subtour eliminating constraints (3) yields an assignment problem, which can be solved in polynomial time
  - Solutions to a relaxed problem typically contains a number of sub-tours
  - Branch on these sub-tours (rather than on fractional variables)
  - Branching ⇔ partitioning of the solution space

#### DRAW AN EXAMPLE

(Ch. 15.4.2)
