

# AMPL aid for the Mexico project

## 1 Getting started

Once you have the model files, you are set to go. The available files are

```
mex.mod (the model file)
mex.dat (the data file)
```

We encourage you to look at the files to understand how the model is structured.

You may now start AMPL by giving the command

```
AMPL
```

AMPL should start up and you get a prompt looking like

```
AMPL:
```

## 2 AMPL

To load the model, write (all commands are terminated by “;”)

```
AMPL: model mex.mod;
```

To load the data, write

```
AMPL: data mex.dat;
```

To obtain the optimal solution, write

```
AMPL: solve;
```

You should get the result

```
MINOS 5.5: optimal solution found.
40 iterations, objective 21607.20587
```

The number is rather low, as the model is expressed in Mton and Mpesos in order to reduce the size of the constants.

You may now take a closer look at the solution. To see the value of a variable use the command `display`. As an example, to see the amount of raw-materials sent from the mines to the mills, write

```
AMPL: display raw_trans;
```

The name of other variables may be found by studying the model. You should get the result

```
raw_trans [*,*]
:      Ahmsa  Fundidora  Hylsa  Hylsap  Sicartsa  :=
Cerro_Mer  2.24      0          0       0       0
Coahuila   5.24836    3.648      0       0       1.824
El_Encino  2.60484    5.84516    0       0       0
Laperla    3.47       0          0       0       0
Lastruchas 0          0          0       0       2.85
Penacol    0          0.220774   2.50418  1.65276  0.0263736
;
```

You may obtain the reduced cost for these variables by writing

```
ampl: display raw_trans.rc;
```

In the same fashion, you may get the dual variables corresponding to the constraint `Raw_Cap` by writing

```
ampl: display Raw_Cap.dual;
```

You may get the slack in the constraints by writing

```
ampl: display Raw_Cap.slack;
```

If you want to aggregate values you may use summation in the displayed expressions. For example, to get the total amount of steel exported, you may write

```
ampl: display sum{i in PRODUCER, c in EXPORTS, p in PRODUCT} prod_trans[i,c,p];
```

If you want to get specific elements you may index the variables and constraints, for example,

```
ampl: display processing['Oven_Red','Ahmsa'];
```

returns the amount produced in the blast-furnace process in Ahmsa.

If you change the model and/or the data and wish to reload them, you must write either

```
ampl: reset;
```

resetting everything, or

```
ampl: reset data;
```

resetting everything from the data-file. If you do not do this, AMPL will complain as AMPL will believe that you are redefining variables and parameters.

Constants may be changed using the command `let`. As an example, the command

```
ampl: let fixed_cost_raw:=40;
```

will increase the fixed cost of transporting raw-materials.

### 3 The most probable mistakes

Q: I wrote a command, but nothing happened. When I write the next command I get weird errors such as

```
syntax error
```

```
context: >>>.....
```

A: You probably forgot a “;” after your last command. If nothing happens, look at the prompt. If it reads

```
ampl?
```

then AMPL is expecting the rest of the last command (perhaps you just forgot a “;” after the command).

Q: I get errors of the type

```
invalid subscript my_variable[j,i]
```

although it has indices i and j.

A: Check the order of your indices.
