

to the symbols and operations of algebra any meanings whatever that will lead to consistency. Although the interpretation ... proves nothing, it may suggest that there is no occasion for anyone to muddle himself into a state of mystic wonderment over nothing about the grossly misnamed "image-beings".

A geometrical representation referred to Wessel and Argand indeed pendently is based on the geometric principle that the altitude to the hypotenuse of a right triangle is a mean proportional between the segments into which the altitude divides the hypotenuse. In Figure [76-1],

of myopic wonderment over nothing about the grossly misnamed "image-beings".

Using the coordinates in the figure, the midpoint of the hypotenuse  $AB$  of right triangle  $AOB$ , and  $C$  is the midpoint of the side  $OB$ . The three vertices in Figure [76]-2 are the vertex of a right triangle  $O$  from midpoints of the three sides  $a$  and  $b$ . An example is the proof that the rectangular coordinates  $a$  and  $b$ . Some interesting geometric proofs can result from the representation of the complex number  $a + bi$  by the point in the plane with tion of the complex number  $a + bi$  by the point in the plane with

Figure [76]-2

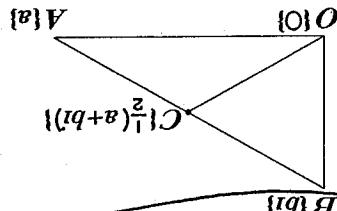

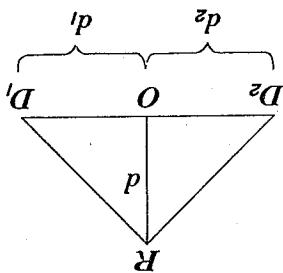

Figure [76]-1

$$\text{Then } d_1 : d = d : d^2. \text{ Now } d = \sqrt{d_1 d_2} = \sqrt{1 \cdot -1} = \sqrt{-1} = i.$$

$d_1 = d_2 = +1$ ,  $OD_1 = d_2 = -1$ .  $\angle D_1 RD_2$  is a right angle, and  $OR = d$ . A geometrical representation referred to Wessel and Argand indeed pendently is based on the geometric principle that the altitude to the hypotenuse of a right triangle is a mean proportional between the segments into which the altitude divides the hypotenuse. In Figure [76-1],

$$OC = \frac{1}{2}(a + bi) - 0 = \frac{1}{2}(a + bi) = \frac{1}{2}\sqrt{a^2 + b^2},$$

and

Using the coordinates in the figure, the midpoint of the hypotenuse  $AB$  of right triangle  $AOB$ , and  $C$  is the midpoint of the side  $OB$ .

All this of course proves nothing. There is nothing to be proved; we assign

of a similar representation it has been said /Bell (d): 234/:

Let  $+1$  designate the positive rectangular unit and  $-1$  a certain other unit perpendicular to the positive unit and having the same origin; then the direction angle of  $+1$  will be equal to  $0^\circ$ , that of  $-1$  to  $180^\circ$ , that of  $+i$  to  $90^\circ$ , and that of  $-i$  to  $-90^\circ$ . By the rule that the direction angle of the product shall equal the sum of the angles of the factors, we have:  $(+1)(+1) = +1$ ;  $(+1)(-1) = -1$ ;  $(-1)(+1) = +1$ ;  $(+1)(-i) = -i$ ;  $(-1)(-i) = +i$ ;  $(+i)(-i) = -1$ ;  $(+e)(+e) = +e$ ;  $(-1)(-e) = -1$ ;  $(+e)(-e) = -e$ ;  $(-1)(-e) = +e$ ;  $(+1)(-e) = -1$ ;  $(-1)(-e) = -1$ ; and  $+1$ ;  $(-e)(-e) = -1$ . From this it is seen that  $e$  is equal to  $\sqrt{-1}$ , and the divergence of the product is determined such that not any of the common rules of operation are contravened.

Walls, Wessel (1798), Jean Robert Argand (1806), Gauss (1813), and others made significant contributions to the understanding of complex numbers through graphical representations, and in 1831 Gauss defined complex numbers as ordered pairs of real numbers for which addition is given as follows /D. E. Smith (e): I, 60/:

$$(a, b) + (c, d) = (ac - bd, ad + bc), \text{ and so forth. Wessel's representation is given as follows /D. E. Smith (e): I, 60/:}$$

$(a, b) + (c, d) = (ac - bd, ad + bc)$

and others made significant contributions to the understanding of complex numbers through graphical representations, and in 1831 Gauss

defined complex numbers as ordered pairs of real numbers for which

addition is given as follows /D. E. Smith (e): I, 60/:

$$20\sqrt{-4}, \text{ or } 40\sqrt{-1}.$$

What shall this side be? We cannot say it is 40, nor that it is of a Negative Square) or (which is equivalent thereto)  $10\sqrt{-16}$ , or

$-1600$ . But thus rather, that it is  $\sqrt{-1600}$ , (the Supposed Root

-40. Because either of these multiplied into itself, will make  $+1600$ ;

What shall this side be? We cannot say it is 40, nor that it is 20  $\sqrt{-4}$ , or 40  $\sqrt{-1}$ .

In his Algebra (1673, republished in 1693 in Opera mathematica; see side [160 square perches = 1 English acre]:

/D. E. Smith (e): I, 48/) John Wallis associated "1600 square perches", with a loss and then supposed this to be in the form of a square with a

loss Algebræ (1673, republished in 1693 in Opera mathematica; see side [160 square perches = 1 English acre]:

With a loss and then supposed this to be in the form of a square with a

loss follows as a good exercise that  $x^2 = -\sqrt{-1}$ , and  $x^2 = 1$ ,  $x^2 = \sqrt{-1}, \dots$ ,

then  $x^2 + 1 = 0$  when  $x$  is replaced by  $i$ , and  $x^2 = \pm\sqrt{-1}$ . Now, if  $i^2 = \sqrt{-1}$ ,

$i^2 + 1 = 0$ , affords an excellent approach to  $i$  and  $i^2$ , as follows:

Bombelli continued Cardano's work. From the equation  $x^2 + a = 0$ ,

Gauss (1832) introduced the term "complex number." William Rowan Hamilton (1832) expressed the complex number in the form of a num-
