On the Milne problem and the hydrodynamic limit for a steady Boltzmann equation model.

L. Arkeryd * & A. Nouri †, ‡

Abstract. For a stationary nonlinear Boltzmann equation in a slab with a particular truncation in the collision operator, the Milne problem for the boundary layer together with a weak type of hydrodynamic behaviour in the interior of the slab, are studied by non-perturbative methods in the small mean free path limit.

1 Introduction

Solutions to half-space problems for the Boltzmann equation play an important role as boundary layers in the study of hydrodynamic limits for solutions to the Boltzmann equation when the mean free path tends to zero. Such problems have been extensively studied in the linear context, using functional analytic and energy methods ([BCN1], [C1], [C2], [G], [GP], [Gu] and others). In the discrete velocity case for the Boltzmann equation a number of problems have been investigated, among them half-space problems for the Broadwell model in [BT] and weak shock wave solutions in [BIU]. The existence of solutions to the half-space problem with given data at one end was proven in [CIPS], as well as their convergence to a set of Maxwellians at infinity. The question whether the limit Maxwellian can be fixed a priori was answered positively in [U] for a fixed Maxwellian at infinity which is close to the given data.

For the BGK and Boltzmann equations, a wide range of similar questions have been addressed by the Kyoto group around Y. Sone and K. Aoki in a perspective of asymptotic analysis and numerical studies. Among their papers in this area we mention [S1], [S2], [SOA1], [SOA2], where extensive

So far there are few purely theoretical results on the half-space problem and the hydrodynamic limit for the fully nonlinear Boltzmann equation with continuous velocities. An existence theorem for the half-space problem was established [GPS] for small data and specular reflection boundary conditions. The hydrodynamic limit of solutions of the (evolutionary) Boltzmann equation [DL] towards solutions of the incompressible Navier-Stokes equations was performed for smooth solutions in [DEL] and for weak solutions in [BGL1], [BGL2], complemented in [BU]. In [BCN2], a kinetic description of a gas between two plates at different temperatures and no mass flux was given in the case of a small mean free path for the nonlinear stationary Boltzmann equation under diffuse reflection boundary conditions.

In this paper, we address the half-space problem for the stationary nonlinear Boltzmann equation in the slab with given indata, for a collision operator truncated for large velocities and for small values of the velocity component in the slab direction. Instead of considering the half-space problem in isolation, it is here studied within a frame of hydrodynamic limits for solutions to the nonlinear stationary Boltzmann equation in the slab. This avoids explicitly dealing with what type of Maxwellians that are permitted at infinity in the half space problem (cf. e.g. [AC], [CGS]). An earlier paper [AN1] considered in the same spirit a fluid approximation inside a bounded domain together with initial and boundary layers for an evolutionary linear Boltzmann model of condensation and evaporation.

Existence of solutions to the nonlinear Boltzmann equation in a bounded slab is proved in [AN2], [AN3] (see also [AN4] and [P] for the related stationary Povzner equation). By the conservation properties of the Boltzmann collision operator, there are in general at most two Maxwellians with the same fluxes as the limit of such solutions, when the mean free path tends to zero. In that limit the existence is proven of solutions to the Milne problem with given indata at the boundary point, and either convergence to one of those two Maxwellians, or collapse at small velocities at spatial infinity. One main ingredient in the techniques of the paper is the use of a kinetic inequality, deduced from the smallness of the entropy production term, for measuring the distance to the set of Maxwellians, see [A], [N].

The plan of the paper is as follows. Section 2 is devoted to preliminaries and a statement of the main results. In Section 3 the existence of solutions to the half-space problem is proven. Section 4 describes the asymptotic behaviour of such half-space solutions, in particular a possible convergence to one of the at most two Maxwellians having the same fluxes as the solution.
Finally Section 5 studies a limiting behaviour with hydrodynamic aspects in the interior of the slab, when the mean free path tends to zero.

2 Preliminaries and statement of results.

An integrable cylindrically symmetric Maxwellian

\[ M(v) := \frac{\rho}{(2\pi T)^{\frac{3}{2}}} e^{-\frac{(\xi-\eta)^2 + \eta^2 + \zeta^2}{2\xi T}}, \quad v = (\xi, \eta, \zeta) \in \mathbb{R}^3, \]

(with \( \rho \geq 0 \) and \( T > 0 \)), is uniquely determined by its three moments

\[ \rho = \int M(v) dv, \quad \rho u = \int \xi M(v) dv, \quad \rho (u^2 + T) = \int v^2 M(v) dv. \]

However, it is well known that for nonzero bulk velocity, there can be zero, one or two Maxweillians with given fluxes

\[ \int \xi M(v) dv, \quad \int \xi^2 M(v) dv, \quad \int \xi v^2 M(v) dv, \]

as stated in the following lemma.

**Lemma 2.1** Let \( (c_i)_{1 \leq i \leq 3} \), with \( c_1 \neq 0 \), be given.

(i) If \( c_2 \leq 0 \) or \( c_1 c_3 \leq 0 \) or \( c_1 c_3 > \frac{25}{16} c_2^2 \), there is no Maxwellian with fluxes \( (c_i)_{1 \leq i \leq 3} \).

(ii) If \( c_1 c_3 = \frac{25}{16} c_2^2 \), there is a unique Maxwellian with fluxes \( (c_i)_{1 \leq i \leq 3} \).

(iii) If \( 0 < c_2^2 < c_1 c_3 < \frac{25}{16} c_2^2 \), there are two Maxweillians with fluxes \( (c_i)_{1 \leq i \leq 3} \).

(iv) If \( c_2^2 \geq c_1 c_3 > 0 \), there is a unique Maxwellian with fluxes \( (c_i)_{1 \leq i \leq 3} \).

For the convenience of the reader, we recall a short proof.

**Proof of Lemma 2.1** The unknown \( \rho, u, T \) defining an integrable Maxwellian \( M \), are solutions to the system

\[ \rho \geq 0, \quad T > 0, \quad \rho u = c_1, \quad \rho (u^2 + T) = c_2, \quad \rho u (u^2 + 5T) = c_3. \quad (2.1) \]

Since \( c_1 \neq 0 \), there are no positive solutions \( \rho \) and \( T \) when \( c_2 \leq 0 \) or \( c_1 c_3 \leq 0 \).

Since \( c_1 \neq 0 \),

\[ \rho = \frac{c_1}{u}, \quad T = \frac{c_2}{c_1} u - u^2, \]

where \( u \) is a solution to

\[ 4c_1 u^2 - 5c_2 u + c_3 = 0, \quad (2.2) \]

\[ c_1 u > 0, \quad u \in [0, \frac{c_2}{c_1}], \quad (2.3) \]
and $]0, \frac{2c_2}{c_1}[\) denotes the open interval with end points 0 and \(\frac{2c_2}{c_1}\). For \(c_1 c_3 > \frac{25}{16} c_2^2\), there is no real solution \(u\) to equation (2.2). For \(c_1 c_3 = \frac{25}{16} c_2^2\), the solution \(\frac{5c_2}{8c_1}\) to equation (2.2) satisfies (2.3). For \(0 < c_2^2 < c_1 c_3 < \frac{25}{16} c_2^2\), both solutions to equation (2.2),

\[
  u_\epsilon = \frac{5c_2 + \epsilon \sqrt{25c_2^2 - 16c_1 c_3}}{8c_1}, \quad \epsilon \in \{-, +\},
\]

satisfy (2.3). For \(c_2^2 \geq c_1 c_3 > 0\), only \(u = \frac{5c_2 - \sqrt{25c_2^2 - 16c_1 c_3}}{8c_1}\) satisfies (2.3). $\Box$

Remark. We note for \(c_1 > 0\) that \(0 \leq u_- \leq u_+, T_+ \leq \frac{3c_2}{5} \leq T_-\). The Mach number is defined by \(M_2^2 = \frac{2c_2}{5c_1}\). Then

\[
  u_+^2 = \frac{c_3 M_2^2}{c_1 (3 + M_2^2)}, \quad T_+ = \frac{3c_3}{5c_1 (3 + M_2^2)}.
\]

With

\[
  \sin^2 \theta = \frac{16c_1 c_3}{25c_2^2}, \quad 0 \leq \theta \leq \frac{\pi}{2},
\]

we get

\[
  M_2^2(\theta) = \frac{3}{4\cot^2 \frac{\theta}{2} - 1}, \quad M_+^2(\theta) = \frac{3}{4\tan^2 \frac{\theta}{2} - 1},
\]

where \(M_-(\theta)\) is subsonic and \(M_+(\theta)\) is supersonic.

Define for \(0 < \mu < \lambda\)

\[
  V_\lambda := \{ v \in \mathbb{R}^3; |v| \leq \lambda \}, \quad V_\lambda' = \{ v \in V_\lambda; \mu \leq |v| \}.
\]

By a perturbative argument there are \(\lambda_0 < \infty\) and \(0 < \mu_0\), so that in the sense of the following lemma, for \(\lambda \geq \lambda_0, 0 < \mu < \mu_0\), (iii-iv) of Lemma 2.1 hold for the Maxwellian fluxes, also when the integrals are truncated with respect to \(V_\lambda'\).

**Lemma 2.2** Let \((c_i)_{1 \leq i \leq 3}\), with \(0 < c_1 c_3 < \frac{25}{16} c_2^2\) and \(c_1 c_3 \neq c_2^2\) be given. There are \(\lambda_0 < \infty\) and \(\mu_0 > 0\), such that for \(\lambda \geq \lambda_0, 0 < \mu < \mu_0\), (iii-iv) of Lemma 2.1 hold for the truncated Maxwellian fluxes

\[
  (c_1, c_2, c_3) = (\int_{V_\lambda} \xi M(v)dv, \int_{V_\lambda} \xi^2 M(v)dv, \int_{V_\lambda} \xi v^2 M(v)dv).
\]
In the case \( c_1 c_3 = c_2^2 \), let \( (\rho_-, u_-, T_-) \) be the values of \( (\rho, u, T) \) for \( \lambda = \infty, \mu = 0 \) when \( \epsilon = - \) in (2.4), and correspondingly \( (\rho_+, u_+, T_+) \) with \( T_+ = 0 \) for \( \epsilon = + \). Given any neighbourhoods \( \mathbf{O}_- \) and \( \mathbf{O}_+ \) of \( (\rho_-, u_-, T_-) \) and \( (\rho_+, u_+, T_+) \) respectively, then \( (\rho(\lambda, \mu), u(\lambda, \mu), T(\lambda, \mu)) \) is either in \( \mathbf{O}_- \) or in \( \mathbf{O}_+ \) for \( \lambda, \mu^{-1} \) large enough. Moreover, \( (\rho(\lambda, \mu), u(\lambda, \mu), T(\lambda, \mu)) \) is uniquely determined in the \( \mathbf{O}_- \)-case.

**Proof of Lemma 2.2.** We discuss the case \( c_1 > 0 \). The case \( c_1 < 0 \) is analogous.

For \( (c_i)_{1 \leq i \leq 3} \) with \( 0 < c_1 c_3 < \frac{25}{16} c_2^2 \), consider

\[
F(\lambda, \mu, \rho, u, T) = (F_1, F_2, F_3)(\lambda, \mu, \rho, u, T),
\]

where

\[
F_1(\lambda, \mu, \rho, u, T) := \frac{\rho}{(2\pi T)^{\frac{3}{2}}} \int_{\mathcal{V}} \xi e^{-\frac{|u-v|^2}{4T}},
\]

\[
F_2(\lambda, \mu, \rho, u, T) := \frac{\rho}{(2\pi T)^{\frac{3}{2}}} \int_{\mathcal{V}} \xi^2 e^{-\frac{|u-v|^2}{4T}},
\]

\[
F_3(\lambda, \mu, \rho, u, T) := \frac{\rho}{(2\pi T)^{\frac{3}{2}}} \int_{\mathcal{V}} \xi u^2 e^{-\frac{|u-v|^2}{4T}}.
\]

At \( (\lambda, \mu, \rho, u, T) \) with \( \rho \geq 0, T > 0, \lambda^{-1} = \mu = 0 \), it holds that

\[
\frac{\partial F_1}{\partial \rho} = u, \quad \frac{\partial F_1}{\partial u} = \rho, \quad \frac{\partial F_1}{\partial T} = 0,
\]

\[
\frac{\partial F_2}{\partial \rho} = u^2 + T, \quad \frac{\partial F_2}{\partial u} = 2\rho u, \quad \frac{\partial F_2}{\partial T} = \rho,
\]

\[
\frac{\partial F_3}{\partial \rho} = u(u^2 + 5T), \quad \frac{\partial F_3}{\partial u} = \rho(3u^2 + 5T), \quad \frac{\partial F_3}{\partial T} = 5\rho u,
\]

and so the Jacobian \( J \) with respect to \( (\rho, u, T) \) of \( F \) at \( (\infty, 0, \rho, u, T) \) is equal to

\[
J = \rho^2 u(3u^2 - 5T).
\]

At any \( (\rho_0, u_0, T_0) \) of Lemma 2.1 such that \( T_0 \neq 0 \), and such that

\[
F(\infty, 0, \rho_0, u_0, T_0) = (c_1, c_2, c_3)
\]

5
with $0 < c_1 c_3 < \frac{24}{16} c_2^2$, it holds that

$$ J = 8c_2^2(u_0 - \frac{5c_2}{8c_1}) \neq 0. $$

Consequently, by the implicit function theorem, there are neighborhoods $V_1$ of $(\infty, 0)$ with $V_1 = \{ \lambda > \lambda_0, 0 \leq \mu < \mu_0 \}$, and $V_2$ of $(\infty, 0; \rho_0, u_0, T_0)$ respectively, and a $C^1$ function $G$ from $V_1$ to $R^3$, so that for $(\lambda, \mu) \in V_1$, $T_0 > 0$, it holds that

$$(c_1, c_2, c_3) = F(\lambda, \mu, \rho, u, T), \quad \text{and} \quad (\lambda, \mu, \rho, u, T) \in V_2$$

iif $(\rho, u, T) = G(\lambda, \mu)$.

The neighbourhoods can be taken locally constant with respect to $c$. Assume that there are other solutions than the above local perturbations for arbitrarily large $\lambda$ and for arbitrarily small $\mu$. Then there is a sequence $(\lambda_n, \mu_n)_{n \in N}$ tending to $(\infty, 0)$, when $n \to +\infty$ and a sequence $(\rho_n, u_n, T_n)_{n \in N}$, satisfying

$$ c = (c_1, c_2, c_3) = F(\lambda_n, \mu_n, \rho_n, u_n, T_n), \quad \rho_n > 0, \quad T_n > 0. \quad (2.6) $$

By the positivity of $c_1$ it follows that $u_n > 0$. Writing $V'_{\lambda_n}$ for $V'_{\lambda}$ with $\lambda = \lambda_n, \mu = \mu_n$, we discuss separately the cases, when $(\rho_n, u_n, T_n)$ is bounded and unbounded.

**Case 1.** $(\rho_n, u_n, T_n)$ is bounded, hence converges (up to a subsequence) to some $(\rho_*, u_*, T_*)$.

**Case 1(i).** $T_* > 0$. Passing to the limit when $n$ tends to $+\infty$ in (2.6) implies that $F(\infty, 0, \rho_*, u_*, T_*) = c$. Hence, by Lemma 2.1, $(\rho_*, u_*, T_*)$ is one of the (at most) two solutions of the case $\lambda = \infty, \mu = 0$. Then, for $n$ large enough, $(\rho_n, u_n, T_n)$ is in a given neighbourhood of $(\rho_*, u_*, T_*)$. Hence in this case only the previous local perturbative Maxwellians exist.

**Case 1(ii).** $T_* = 0, u_* \neq 0$. Then $\frac{\rho_n}{(2\pi T_n)^{\frac{3}{2}}} e^{-\frac{|u-u_n|^2}{2T_n}}$ converges for the weak* topology of bounded measures to $\rho_* \delta_{v=u_*}$. Hence,

$$ c_2^2 = \lim_{n \to +\infty} \frac{\rho_n}{(2\pi T_n)^{\frac{3}{2}}} \int_{V'_{\lambda_n}} \xi^2 e^{-\frac{|u-u_n|^2}{2T_n}} \, dv = (\rho_* u_*^2)^2 $$

$$ = (\rho_* u_*) (\rho_* u_*^2) = \lim_{n \to +\infty} \frac{\rho_n}{(2\pi T_n)^{\frac{3}{2}}} \int_{V'_{\lambda_n}} \xi e^{-\frac{|u-u_n|^2}{2T_n}} \, dv $$

$$ \lim_{n \to +\infty} \frac{\rho_n}{(2\pi T_n)^{\frac{3}{2}}} \int_{V_{\lambda_n}} \xi v^2 e^{-\frac{|u-u_n|^2}{2T_n}} \, dv = c_1 c_3, $$

6
and \((\rho_*, u_*, T_*) = (\rho_+, u_+, T_+)\) in the notation of (2.4).

**Case 1(iii).** \(T_* = 0, u_* = 0\). Then

\[
c_1 = \lim_{n \to +\infty} \frac{\rho_n}{(2\pi T_n)^{\frac{3}{2}}} \int_{V_n'} \xi e^{-\frac{|v-x_n|^2}{2T_n}} dv
\]

\[
\leq \lim_{n \to +\infty} \frac{\rho_n}{(2\pi T_n)^{\frac{3}{2}}} \int_{V_n'} |\xi| e^{-\frac{|v-x_n|^2}{2T_n}} dv
\]

\[
\leq \lim_{n \to +\infty} \frac{\rho_n}{\sqrt{\pi}} \int |u_n + x\sqrt{2T_n}| e^{-x^2} dx = 0,
\]

which contradicts the assumption \(c_1 > 0\).

**Case 2(i).** The sequence \((\rho_n, u_n, T_n)\) is unbounded with - for a subsequence - \(\lim_{n \to +\infty} u_n = +\infty\). Then, for any \(A > 0\) there is \(n_A \in \mathbb{N}\), such that for \(n \geq n_A\),

\[
\frac{\rho_n}{(2\pi T_n)^{\frac{3}{2}}} \int_{\xi > 2A, |v| < \lambda_n} \xi e^{-\frac{|v-x_n|^2}{2T_n}} dv > \frac{c_1}{2}.
\]

Then,

\[
c_2 = \lim_{n \to +\infty} \frac{\rho_n}{(2\pi T_n)^{\frac{3}{2}}} \int_{\xi < \lambda_n, |\xi| > \mu_n} \xi^2 e^{-\frac{|v-x_n|^2}{2T_n}} dv
\]

\[
> \lim_{n \to +\infty} \frac{2A \rho_n}{c_1(2\pi T_n)^{\frac{3}{2}}} \int_{\xi > 2A, |v| < \lambda_n} \xi e^{-\frac{|v-x_n|^2}{2T_n}} dv > \frac{c_1 2A}{2 c_1} = A,
\]

which contradicts the finiteness of \(c_2\).

**Case 2(ii)** \(\lim_{n \to +\infty} T_n = +\infty, \lim_{n \to +\infty} u_n = u_* \geq 0\) and finite. Then,

\[
0 < c_1 = \lim_{n \to +\infty} \frac{\rho_n}{(2\pi T_n)^{\frac{3}{2}}} \int_{V_n'} \xi e^{-\frac{|v-x_n|^2}{2T_n}} dv
\]

\[
\leq \lim_{n \to +\infty} \frac{\rho_n}{(2\pi T_n)^{\frac{3}{2}}} \int_{V_n'} |\xi| e^{-\frac{|v-x_n|^2}{2T_n}} dv.
\]

Analogously,

\[
c_2 = \lim_{n \to +\infty} \frac{\rho_n}{(2\pi T_n)^{\frac{3}{2}}} \int_{V_n'} \xi^2 e^{-\frac{|v-x_n|^2}{2T_n}} dv
\]

\[
\geq \frac{1}{2} \lim_{n \to +\infty} \frac{\rho_n}{(2\pi T_n)^{\frac{3}{2}}} \int_{V_n'} \xi^2 e^{-\frac{|v-x_n|^2}{2T_n}} dv.
\]
In this case the integral representation of a bound from below of $\frac{2}{c_1}$ has infinite limit when $n \to \infty$, which leads to a contradiction.

Case 2(iii). The sequence $(\rho_n, u_n, T_n)$ is unbounded and the sequences $(u_n)$ and $(T_n)$ are bounded. Then

$$(c_1, c_2, c_3) = \frac{\rho_n}{(2\pi T_n)^{\frac{3}{2}}} \int_{\nu_n} \xi(1, \xi, v^2)e^{-\frac{(v-n)^2}{2\pi n}} \, dv$$

coincides with the limit when $n \to \infty$ of

$$(c_1^n, c_2^n, c_3^n) = \frac{\rho_n}{(2\pi T_n)^{\frac{3}{2}}} \int_{|\xi| > \mu_n} \xi(1, \xi, v^2)e^{-\frac{(v-n)^2}{2\pi n}} \, dv.$$ 

For $T_* > 0$ this contradicts the boundedness of $c_2$. If $T_* = 0, u_* > 0$, then

$$0 = \lim_{n \to \infty} \frac{c_2^n}{\rho_n} = \lim_{n \to +\infty} \frac{1}{(2\pi T_n)^{\frac{3}{2}}} \int_{|\xi| > \mu_n} \xi^2 e^{-\frac{(v-n)^2}{2\pi n}} \, dv = \lim_{n \to +\infty} u_n^2 = u_*^2 > 0,$$

which is impossible. It remains the case $T_* = u_* = 0$. Then

$$c_1 = \lim_{n \to +\infty} \frac{\rho_n}{\sqrt{2\pi T_n}} \int_{\mu_n}^{+\infty} \xi (e^{-\frac{((x-n)^2)}{2\pi n}} - e^{-\frac{(x+n)^2}{2\pi n}}) \, d\xi.$$ 

Hence, by an integration by parts,

$$c_1 = \lim_{n \to +\infty} \left\{ \rho_n \sqrt{\frac{T_n}{2\pi}} (e^{-\frac{(x-n)^2}{2\pi n}} - e^{-\frac{(x+n)^2}{2\pi n}}) ight\} + \rho_n u_n \int_{\mu_n}^{+\infty} (e^{-\frac{(x-n)^2}{2\pi n}} + e^{-\frac{(x+n)^2}{2\pi n}}) \, dx. \quad (2.7)$$

Analogously,

$$c_2 = \lim_{n \to +\infty} \left\{ \rho_n \sqrt{\frac{T_n}{2\pi}} (\mu_n (e^{-\frac{(x-n)^2}{2\pi n}} + e^{-\frac{(x+n)^2}{2\pi n}}) ight\} + \mu_n \int_{\mu_n}^{+\infty} (e^{-\frac{(x-n)^2}{2\pi n}} + e^{-\frac{(x+n)^2}{2\pi n}}) \, dx \right\} + u_n c_1 \right\}. \quad (2.8)$$

Finally,

$$c_3 = \lim_{n \to +\infty} \left\{ (u_n^2 + 2T_n) c_1 + u_n \rho_n \mu_n \sqrt{\frac{T_n}{2\pi}} (e^{-\frac{(x-n)^2}{2\pi n}} + e^{-\frac{(x+n)^2}{2\pi n}}) ight\} + \rho_n (\mu_n^2 + 2T_n) \left\{ \sqrt{\frac{T_n}{2\pi}} (e^{-\frac{(x-n)^2}{2\pi n}} - e^{-\frac{(x+n)^2}{2\pi n}}) ight\} + 3 \rho_n u_n \int_{\mu_n}^{+\infty} (e^{-\frac{(x-n)^2}{2\pi n}} + e^{-\frac{(x+n)^2}{2\pi n}}) \, dx \right\}. \quad (2.9)$$
By (2.7) and (2.8),

$$ u_n \rho_n \mu_n \sqrt{\frac{T_n}{2\pi}} \left( e^{-\frac{(y_n-z_n)^2}{2T_n}} + e^{-\frac{(y_n+z_n)^2}{2T_n}} \right) < c_2 u_n, $$

$$ \rho_n (\mu_n^2 + 2T_n) \sqrt{\frac{T_n}{2\pi}} \left( e^{-\frac{(y_n-z_n)^2}{2T_n}} - e^{-\frac{(y_n+z_n)^2}{2T_n}} \right) < c_1 (\mu_n^2 + 2T_n), $$

$$ \rho_n u_n \sqrt{\frac{T_n}{2\pi}} \int_{\mu_n}^{+\infty} \left( e^{-\frac{(y-x)^2}{2T_n}} + e^{-\frac{(y+x)^2}{2T_n}} \right) < c_1 T_n. $$

Consequently, in the limit when \( n \to +\infty \) in (2.9), \( c_3 = 0 \) which contradicts the hypotheses.

We have thus proved that for \( c_1 c_3 \neq c_2^2 \) there are only the perturbative Maxwellian solutions. For \( c_1 c_3 = c_2^2 \) and \( (\lambda, \mu) \) close enough to \( (\infty, 0) \), the above proof implies that either the Maxwellian is of perturbative type connected to \( T_- \), or that the \( O_+ \)-situation holds. \( \square \)

**Remark.** When \( c_1 c_3 = c_2^2 \), it is the discussion in 1(ii) that only leads to the \( O_+ \)-control instead of the stronger uniqueness results that follows from the implicit function theorem in the other cases. We do not exclude that a more detailed analysis also in this case might prove the same type of uniqueness as when \( c_1 c_3 \neq c_2^2 \).

For \( c_1 c_3 < 0 \) or \( c_1 c_3 > \frac{25}{16} c_2^2 \), and \( (\lambda, \mu) \) close enough to \( (\infty, 0) \), the above proof implies that there is no Maxwellian with such \( c \)-values and satisfying (2.5). For \( c_1 c_3 = \frac{25}{16} c_2^2 \) and any neighbourhood \( O \) of \( (\rho_-, u_-, T_-) = (\rho_+, u_+, T_+) \), the above proof implies that \( (\rho(\lambda, \mu), u(\lambda, \mu), T(\lambda, \mu)) \) is in \( O \) for \( \lambda, \mu^{-1} \) large enough.

For the stationary Boltzmann equation in a slab with given indata on the boundary the following result was proved in [AN3].

**Lemma 2.3** Consider a slab \(-a \leq x \leq a\) with \( \xi \) the component of the velocity \( v \in \mathbb{R}^3 \) in the \( x \)-direction. Let indata \( f_0 \) be given on the boundary with

$$ \int_{-\xi > 0} [\xi (1 + |v|^2 + |\log f_0|) + (1 + |v|^\beta)] f_0(\epsilon a, v) dv < \infty, \quad \epsilon \in \{-1, 1\}. $$

Given \( \beta \) with \( 0 \leq \beta < 2 \) and \( m > 0 \), there is a weak solution to the stationary Boltzmann equation such that \( \int (1 + |v|^\beta) f(x, v) dv = m \), and with indata
kfb for some $k > 0$.

Given $\beta$ with $-3 < \beta < 0$ and $m > 0$, there is a mild solution to the stationary Boltzmann equation such that $\int f(x,v)dxdv = m$, and with indata $kfb$ for some $k > 0$.

In the sequel we shall also need a result relating the distance of density functions from the set of Maxwellians, to the magnitude of the collision integrand.

**Lemma 2.4** Consider a set of non-negative functions $f$ that is weakly compact in $L^1(\mathbb{R}^3)$. Given $\epsilon, \eta > 0$, there is $\delta > 0$, such that if

$$| ff_* - ff'_* | < \delta$$

in $V^1 \times V^1 \times S^2$ outside of some subset of measure smaller than $\delta$, then for some Maxwellian $M_f$ (depending on $f$),

$$\int_{V^1 \times S^2} | f - M_f | dv < \epsilon.$$

Lemma 2.4 was proved in the $\mathbb{R}^3$ case in [A] and [N]. From those proofs the present local version can be obtained similarly to the way the corresponding result for the functional equation $ff_* - ff'_* = 0$ was localized in [W].

Denote by $(\xi, \eta, \zeta)$ the three components of $v \in \mathbb{R}^3$ and set $\sigma = \sqrt{\eta^2 + \zeta^2}$.

In this paper, the hydrodynamic limit is considered for subsequences of $f^\epsilon$, solutions to

$$\xi \frac{\partial f^\epsilon}{\partial x} = \frac{1}{\epsilon} Q(f^\epsilon, f^\epsilon), \quad x \in [-1, 1], \quad v \in \mathbb{R}^3, \quad (2.10)$$

$$f^\epsilon(-1, v) = M_l(v), \quad \xi > 0, \quad f^\epsilon(1, v) = M_r(v), \quad \xi < 0, \quad (2.11)$$

when the mean free path $\epsilon$ tends to zero. Here

$$M_l(v) := \frac{\rho_l}{(2\pi T_l)^{3/2}} e^{-\frac{v^2}{2T_l}}, \quad M_r(v) := \frac{\rho_r}{(2\pi T_r)^{3/2}} e^{-\frac{v^2}{2T_r}},$$

and

$$Q(f, f)(x,v) := \int_{\mathbb{R}^3 \times S^2} b(\theta) \chi(v, v_*, \omega) | v - v_* |^\beta (f f'_* - f f_*) dv_* d\omega,$$
\[ \theta \in (0, \pi) \text{ is the azimuthal angle between } v - v_* \text{ and } \omega, \]

\[ f_*= f(x, v_*), \quad f' = f(x, v'), \quad f'_*= f(x, v'_*), \]

\[ v^* = v - (v - v_*, \omega), \quad v'_* = v_*(v - v_*, \omega). \]

Moreover,

\[ \chi(v, v_*, \omega) = 0 \quad \text{if} \quad |v| \geq \lambda, \text{or} \quad |v_*| \geq \lambda, \text{or} \quad |v'| \geq \lambda, \text{or} \quad |v'_*| \geq \lambda, \]

or \[ |\xi| \leq \mu, \text{or} \quad |\xi_*| \leq \mu, \text{or} \quad |\xi'| \leq \mu, \text{or} \quad |\xi'_*| \leq \mu, \]

\[ \chi(v, v_*, \omega) = 1 \quad \text{else,} \quad \beta \in [0, 2], \quad b \in L^1_{+}(0, \pi), \quad b(\theta) \geq c > 0, \quad a.e. \]

For \( \lambda \) finite, the factor \(|v - v_*|^\beta\) only introduces minor changes in the arguments, so we shall only discuss the case \( \beta = 0 \). Under the boundary conditions (2.11), there are cylindrically symmetric (with respect to the variables \((\xi, \sigma)\)) functions \( f^* \) solutions to (2.10-11). Only such solutions are considered in the following. In particular,

\[ \int \xi \eta f^*(x, v)dv = \int \xi \zeta f^*(x, v)dv = 0 \]

under the cylindrical symmetry. By Green’s formula the fluxes

\[ (c^*_{i})_{1 \leq i \leq 3} = \left( \int_{|\xi| \geq \mu, |v| \leq \lambda} \xi (1, \xi, v^2) f^*(x, v)dv \right) \]

are constant in \( x \) with \( \epsilon \)-independent bounds determined by \( M_l \) and \( M_r \). Denote by \((c^*_{i})_{1 \leq i \leq 3}\) a converging subsequence with limit \((c_i(\lambda, \mu))_{1 \leq i \leq 3}\), when \( \epsilon \rightarrow 0 \). Either \( c_1(\lambda, \mu) = 0 \) or \( c_1(\lambda, \mu) \neq 0 \). In this paper we only discuss such sequences of solutions with \( c_1(\lambda, \mu) \neq 0 \), and then - possibly after a change of \( x \)-direction - take \( c_1(\lambda, \mu) > 0 \), also requiring \( c^*_{i} > 0 \) for all \( j \). Such systems can be considered to model an evaporation-condensation situation with evaporation at \( x = -1 \) and condensation at \( x = 1 \). We shall further assume (for a subfamily in \( \lambda, \mu \)) the existence of \( \lim_{\lambda, \mu \rightarrow -\infty} c_i(\lambda, \mu) = c_i \), for \( i = 1, 2, 3 \), with \( c_1 > 0 \). The quantities \( \lambda_0 \) and \( \mu_0 \) as defined in Lemma 2.2 may be taken locally constant with respect to \((c_1, c_2, c_3)\) satisfying the conditions of the lemma, and with \( \lambda_0, \mu_0^{-1} \) so large that negative \( T \)'s are excluded. From here on we only consider such \( \lambda \geq \lambda_0, 0 < \mu \leq \mu_0 \), and \( 0 < c_1 c_3 < \frac{25 c_2^2}{16} \).
The main results established in this paper are contained in the following three theorems.

**Theorem 2.5** Denote by
\[ g^\varepsilon(x, v) := f(x, v), \quad a.a. \ x \in [-1, 1], \quad v \in \mathbb{R}^3. \]
Then there is a sequence \( (\varepsilon_j) \) with \( \lim_{j \to \infty} \varepsilon_j = 0 \), such that \( (g^{\varepsilon_j}) \) converges weakly in \( L^1([-1, 1] \times \mathbb{R}^3) \) to a function \( g \), which is a weak solution to the half-space problem
\[ \xi \frac{\partial g}{\partial x} = Q(g, g), \quad x \geq 0, \quad v \in \mathbb{R}^3, \quad g(0, v) = M_1(v), \quad \xi > 0, \]
in the sense that for any \( x_0 > 0 \), for any test function \( \varphi \) with support in \( [0, x_0] \times V'_X \)
\[ \int_{\xi > 0} \xi M_1(v) \varphi(0, v) dv + \int_0^{x_0} \int_{\mathbb{R}^3} (\xi \frac{\partial \varphi}{\partial x} + Q(g, g) \varphi) dx dv = 0. \]

**Remark.** In this paper test functions are \( L^\infty \)-functions, differentiable in the \( x \)-variable for a.e. \( v \in V'_X \) with \( \varphi(0, v) = 0 \) for \( \xi < 0 \).
An analogous result holds for \( h^\varepsilon(x, v) := f_\varepsilon(x, v) \) and \( M_\varepsilon \).

**Theorem 2.6** Denote by \( S_\delta \) the union of \( \{ v \in V'_X; \mu \leq | x | \leq | x | + \delta \} \) and \( \{ v \in V'_X; | x | \leq | x | + \delta, \xi \leq \delta \} \). If \( c_1c_3 = c_2^2 \), then include in \( S_\delta \) also a \( \delta \)-neighbourhood in \( V'_X \) of \( (\frac{\varphi}{c_1}, 0, 0) \). Either for all \( \delta > 0 \)
\[ \lim_{x \to \infty} \int_{V'_X \setminus S_\delta} g(x, v) dv = 0, \]
or
\[ \lim_{x \to \infty} \int | g(x, v) - M(v) | dv = 0, \]
or
\[ \lim_{x \to \infty} \int | g(x, v) - M_+ (v) | dv = 0 \]
in the case \( c_1c_3 \neq c_2^2 \), respectively
\[ \lim_{x \to \infty} \inf \int | g(x, v) - M_\lambda(v) | dv = 0 \]
in the case \( c_1c_3 = c_2^2 \). Here \( M_-, M_+ \) are those defined in Lemma 2.2, and in the notations of that lemma the infimum is taken over \( M_\lambda \mu \) corresponding to \( O_+ \) and satisfying (2.5).
Remark. The solution $g$ of the half-space problem in Theorem 2.5 satisfies the Milne problem in the sense of Theorem 2.6. The $M_+$-alternative is only possible in the case (iii) of Lemma 2.2.

Theorem 2.7 Suppose $c_1 c_3 \neq c_2^2$. There is a sequence $(\epsilon_j)$ such that
\[ \lim_{j \to \infty} \epsilon_j = 0, \] and $(f^{\epsilon_j})$ converges in weak$^*$ sense to a non-negative element $f$ of $L^1((-1,1); \mathcal{M}(V_\lambda'))$ that satisfies
\[ \int_{V_\lambda'} \xi(1,\xi, v^2) f(x,v) dv = (c_1(\lambda,\mu), c_2(\lambda,\mu), c_3(\lambda,\mu)). \]

Moreover, there are measurable non-negative functions $\theta_-(x), \theta_+(x)$ with $0 \leq \theta_-(x) + \theta_+(x) \leq 1$, $-1 \leq x \leq 1$, such that for test functions $\phi$ with support in $V_\lambda' \setminus S_\delta$ for some $\delta > 0$,
\[ \int \phi f(x,v) dv = \int (\theta_- M_- + \theta_+ M_+) \phi dv. \]

Here we have written $f(x,v) dv$ for the measure in the $v$-variable defined by $f(x, \cdot)$.

Remark. Also for this theorem, there is a (more involved) version in the case $c_1 c_3 = c_2^2$.

3 Boundary layer analysis and the half-space problem.

This section is devoted to a proof of Theorem 2.5. The theorem is an immediate consequence of Lemma 3.1-3 below.

Lemma 3.1 The family $(g^\epsilon)$ is weakly compact in $L^1((0,x_0) \times V_\lambda')$.

Proof of Lemma 3.1. Since
\[ \int g^\epsilon(x,v) dx dv \leq \frac{1}{\mu^2} \int \int g^\epsilon(x,v) dx dv, \]
$(g^\epsilon)$ is uniformly bounded in $L^1((0,x_0) \times V_\lambda')$. It remains to prove the uniform equiintegrability of $(g^\epsilon)$ in $L^1((0,x_0) \times V_\lambda')$. If $(g^\epsilon)$ were not uniformly
equiintegrable on \((0, x_0) \times V'_\lambda\), then there would be a number \(\eta > 0\), a sequence of subsets \(V_j\) of \((0, x_0) \times V'_\lambda\), and a subsequence of \((g^s)\), denoted by \((g_{j})\), such that

\[
\epsilon_j \to 0, \quad |V_j| < \frac{1}{j^2}, \quad \text{and} \quad \int_{V_j} g_j(x, v) dx dv > \eta. \tag{3.1}
\]

Denote by

\[
B_j = \{x \in (0, x_0); \{v \in V'_\lambda; (x, v) \in V_j\} \geq \frac{1}{j}\},
\]

and by

\[
W_j(x) = \{v \in V'_\lambda; (x, v) \in V_j\}, \quad x \in (0, x_0).
\]

Then \(|B_j| \leq \frac{1}{j}\), so that

\[
\int_{B_j} \int_{W_j(x)} g_j(x, v) dv dx > \frac{\eta}{2},
\]

for \(j\) large enough. Only consider \(j\) so large that

\[
\frac{c_2(\lambda, \mu)}{2} \leq \int \xi^2 g_j(x, v) dv \leq 2c_2(\lambda, \mu).
\]

Set

\[
B'_j = \{x \in B_j; \int_{W_j(x)} g_j(x, v) dv > \frac{\eta}{4x_0}\},
\]

\[
W'_j(x) = \{v \in W_j(x); g_j(x, v) > \frac{j\eta}{8x_0}\}.
\]

It holds that

\[
\int_{B'_j} dx \int_{W'_j(x)} g_j(x, v) dv > \frac{\eta}{4}.
\]

And so for \(x \in B'_j\),

\[
\int_{W'_j(x)} g_j(x, v) dv > \frac{\eta}{8x_0},
\]

together with

\[
\int_{B'_j} dx \int_{W'_j(x)} g_j(x, v) dv > \frac{\eta}{8}.
\]
Using the exponential form of the equation for \( g_j \), it follows for \( x \leq x_0 \), 
\( \lambda \geq \xi \geq \mu \), that \( g_j(x,v) \geq e^{c x_0} M_t(v) \), where \( c > 0 \) is independent of \( j \).

Set \( V'_j(x) = \{ v \in V'_\lambda; g_j(x,v) \leq \frac{2 c j}{\delta \mu^2} \} \). Then \( | V'_\lambda - V'_j(x) | < \delta \). Let \( x \in B'_j \), \( v \in W'_j(x) \) be given. It follows that there is a subset \( W_j(x,v) \subset V'_j \times S^2 \) with measure uniformly in \( x, v, j \) bounded from below by a positive constant, such that for \( (v_*, \omega) \in W_j(x,v) \) it holds that

\[
g_j(x,v_*) \geq e^{-c x_0} \inf_{V'_\lambda} M_t(v),
\]

and that

\[
\frac{2 c j}{\delta \mu^2} \geq \max(g_j(x,v'),g_j(x,v_*)).
\]

Hence,

\[
g_j(x,v)g_j(x,v_*) - g_j(x,v')g_j(x,v_*) \geq c g_j(x,v), \tag{3.2}
\]

\[
g_j(x,v)g_j(x,v_*) \geq c j.
\]

Integrating (3.2) over

\[
K_j := \{ (x,v,v_*, \omega); x \in B'_j, v \in W'_j(x), (v_*, \omega) \in W_j(x,v) \},
\]

leads to

\[
c \eta < \frac{1}{\ln j} \int_{K_j} b(\theta) \chi(v,v_*,\omega) g_j(x,v) g_j(x,v_*) \ln \frac{g_j(x,v) g_j(x,v_*)}{g_j(x,v') g_j(x,v_*)} dx dv d\omega < \frac{c'}{\ln j},
\]

which is impossible for \( j \) large enough. \( \square \)

**Lemma 3.2** The family \((Q^{\pm}(g^e, g^e))\) is weakly compact in any \( L^1((0,x_0) \times V'_\lambda)\).

**Proof of Lemma 3.2.** It is sufficient to prove the weak compactness of \((Q^- (g^e, g^e))\). Then the compactness of \((Q^+ (g^e, g^e))\) will follow from the weak compactness of \((Q^- (g^e, g^e))\) together with the boundedness of the entropy production term. And so it is enough to prove the weak \( L^1 \) compactness of \((g^e g^e)\). If this family were not compact, then for some \( \eta > 0 \), there would be a family \((\epsilon_j)\) and a family of sets \( B_j \subset [0,x_0] \times V'_\lambda \times V'_\lambda \) with

\[
| B_j | < \frac{1}{j^2} \text{ and } \int_{B_j} g_j g_j dv dv_* > \eta.
\]

15
But then for each \( j \), there would be a subset of \([0, x_0]\) of measure not exceeding \( \frac{1}{j} \), outside of which the set \( A_x \) of \((v, v_*)\) such that \((x, v, v_*) \in B_j\), has measure bounded by \( \frac{1}{j} \). Since \( \int g_j(x, v) dv \leq \frac{2c_2}{\mu^2} \), the integral of \( g_j g_{j^*} \) over the first set is of magnitude \( \leq \frac{1}{j} \). For \( x \) from the second set, \[
\int_{A_x} g_j g_{j^*} dv \leq \frac{2c_2}{\mu^2} \sup_{A'_x} \int_{A'_x} g_j dv, \]
for \( A'_x \subset V'_\lambda, |A'_x| < j^{-\frac{2}{\mu}} \). An application of Lemma 3.1 completes the proof.

Also using the regularizing properties of the equation, we get

**Lemma 3.3** Denote by \( g \) the weak \( L^1 \) limit in \((0, x_0) \times V'_\lambda\) of a converging sequence of \((g_j)\) with \( \lim \epsilon_j = 0 \). For any test function \( \varphi \) defined on \((0, x_0) \times V'_\lambda\),

\[
\lim_{j \to +\infty} \int_{(0, x_0) \times V'_\lambda} \varphi Q^\pm (g_j, g_j)(x, v) dx dv = \int_{(0, x_0) \times V'_\lambda} \varphi Q^\pm (g, g)(x, v) dx dv.
\]

This can be proved similarly to the corresponding (more involved) result in the time-dependent case [DL].

In Section 4 an entropy dissipation estimate for the half-space solution \( g \) will be needed.

**Lemma 3.4** \( \int b(x) (g_\epsilon - g'_\epsilon) \log \frac{g_\epsilon}{g'_\epsilon} dx dv d\omega \leq c \), where the constant \( c \) only depends on the boundary values.

This easily follows from the corresponding inequality for \( g^\epsilon \), the weak \( L^1 \) compactness of \((g^\epsilon g'^\epsilon)\) in the proof of Lemma 3.2, and the convexity of the entropy-dissipation integrand.

### 4 The behaviour at infinity in the boundary layer.

This section is devoted to a proof of Theorem 2.6.

**Proof of Theorem 2.6.** By the weak \( L^1 \) convergence and by the conservation properties, in the notation of Lemma 3.3,

\[
\int (\xi, \xi^2, \xi v^2) g(x, v) dv = \lim_{j \to +\infty} \int (\xi, \xi^2, \xi v^2) g_j(x, v) dv.
\]
Recall that in the present setup, by Lemma 2.1-2 there are at most two Maxwellians $M_-$ and $M_+$ of perturbation type such that

$$
\int (\xi, \xi \xi^2) M_i(v) dv = \int (\xi, \xi \xi^2) g(x, v) dv = (c_1, c_2, c_3),
$$

$$
x \in \mathbb{R}^+, i \in \{+, -\}.
$$

Recall that for $c_j = \lim_{\lambda \mu^{-1} \to \infty} c_j(\lambda, \mu)$ with $0 < 16c_1c_3 < 25c_2^2$, (cf Section 2 just before the statement of Theorem 2.6), and with $c_1c_3 \neq c_2^2$, the constants $0 < \mu_0$, and $0 < \lambda_0$ are fixed, so that for $0 < \mu \leq \mu_0$, $\lambda_0 \leq \lambda$ the corresponding $c_j(\lambda, \mu), j = 1, 2, 3$, still define the same number (one or two) of Maxwellians. In the case $c_1c_3 = c_2^2$, the set $S_\delta$ as defined in Theorem 2.6 also contains a $\delta$-neighbourhood of $(\frac{c_1}{c_3}, 0, 0)$, and $M_+$ is replaced by an $O_+$ based family $\mathcal{F}$ of $\lambda, \mu$-truncated Maxwellians satisfying (2.5).

Either for all $\delta > 0$

$$
\lim_{x \to \infty} \int_{V'_\lambda \setminus S_\delta} g(x, v) dv = 0,
$$

(4.1)

or for some $\delta > 0$ and some sequence $(x_j)$ tending to infinity,

$$
\int_{V'_\lambda \setminus S_\delta} g(x_j, v) dv > 2\delta.
$$

(4.2)

In the latter case $g(x, \cdot)$ converges in $L^1(V'_\lambda)$ to either $M_-$, $M_+$, or in the the case $c_1c_3 = c_2^2$ to the family $\mathcal{F}$, as will now be proved.

Uniform continuity of $g(x, \cdot)$ in the $L^1(V'_\lambda)$-norm follows from the equation for $g$ and from $\sup_x \int |Q(g, g)(x, v)| dv < \infty$. This means that given $\alpha > 0$, there is $a(\alpha) > 0$ such that

$$
\int_{V'_\lambda} |g(x, v) - g(y, v)| dv < \alpha,
$$

for $|x - y| < a(\alpha)$. Take $\alpha = \delta$ so that for $a_1 = a(\delta)$ by (4.2),

$$
\int_{V'_\lambda \setminus S_\delta} g(x, v) dv > \delta
$$

(4.3)

for $|x - x_j| \leq a_1, j \in \mathbb{N}$. Set

$$
G(x) = \int b\chi(g'g' - gg) \log \frac{g'g'}{gg} (x, v, v_*, \omega) dv dv_* d\omega,
$$

17

$$
and (if necessary) take a subsequence \((x_j)\) so that \(x_{j+1} - x_j > a_1, j \in \mathbb{N}\). It follows from \(\int_0^{+\infty} G(x)dx < +\infty\) that

\[
\Sigma_j \int_{x_j - a_1}^{x_j + a_1} G(x)dx = \int_{-a_1}^{a_1} (\Sigma_j G(y + x_j))dy < +\infty,
\]

hence \(\lim_{j \to +\infty} G(y + x_j) = 0\) a.e. in \([-a_1, a_1]\). For such an \(y\), the subsequence \((g(x_j + y, \cdot))\) is weakly \(L^1(V'_\lambda)\) compact. Only the uniform equi-integrability has to be discussed, and that follows similarly to the proof of Lemma 3.1, but using the estimate \((4.2)\) instead of estimating \(g(x, v_\ast)\) from below using boundary values. For this we start from such an \(y\) with

\[
\int_{V'_\lambda \setminus S_\delta} g(x_j + y, v_\ast) dv_\ast > \delta, \quad \lim_{j \to +\infty} G(x_j + y) = 0.
\]

Write \(g_j(v) := g(x_j + y, v)\). A Dirac measure limit for a subsequence of \(g_j\) at \(v = v_0\) implies \(\xi_0 \geq \mu + \delta, \sigma_0 = 0\), and is excluded when \(c_1c_3 \neq c_2^2\), and by the condition on \(S_\delta\) also when \(c_1c_3 = c_2^2\). Instead the following holds for some \(d \in ]0, \delta[\). For all \(v_0 \in V'_\lambda\) and all \(j \in \mathbb{N}\),

\[
\int_{|v-v_0| \geq d} g_j(v)dv \geq d. \tag{4.4}
\]

If \((g_j)\) is not uniformly equi-integrable, then there are a constant \(\eta > 0\) and a sequence of subsets \((V_j)\) of \(V'_\lambda\) with \(|V_j| \leq \frac{1}{j^r}\), such that

\[
\int_{V_j} g_j(v) dv > \eta.
\]

Similarly to Lemma 3.1 this is contradicted using an entropy dissipation argument. Consider the following three cases.

Either

\[
\int_{W_{j_1}} g_j(v)dv \geq \frac{\eta}{3}, \tag{4.5}
\]

where \(W_{j_1} := \{v \in V_j \cap S_\delta; \sigma \leq 10^{-3}d\}\). Or

\[
\int_{W_{j_2}} g_j(v)dv \geq \frac{\eta}{3}, \tag{4.6}
\]

where \(W_{j_2} := V_j \setminus S_\delta\). Or

\[
\int_{W_{j_3}} g_j(v)dv \geq \frac{\eta}{3}, \tag{4.7}
\]
where \( W_{j3} := \{ v \in V_j \cap S_{\frac{\xi}{4}} : \sigma \geq 10^{-3}d \} \). For any \( v \) in \( W_{jk}, k = 1, 2, 3 \), the contradiction follows from delineating for each \( j \) a set of \( v_* \)'s with volume uniformly bounded from below by a positive constant, where \( g_j(v_*) \) is uniformly in \( v_* \) and \( j \) bounded away from zero, together with for each \( j \) and \( v_* \) a set of \( \omega \)'s in \( S^2 \) of measure uniformly bounded away from zero, that generate (from above) uniformly bounded \( g_j(v'), g_j(v'_*) \), so that the entropy dissipation argument applies.

Case 1(i). The bound (4.5) holds. Also using (4.3), assume in this case that \( \int_{W_j} g_j(v_*)d\omega \geq \frac{\eta}{6} \), where

\[
W_* := \{ v_* \in V'_\lambda \setminus S_{\delta/4} : \sigma \geq 10^{-3}d, g_j(v_*) > \frac{\delta}{4|V'_\lambda|} \}.
\]

\( W_* \) is invariant under rotation around the \( \xi \)-axis. Taking \( v \in W_{j1} \), there is sufficient volume of \( v_* \in W_* \) and \( \omega \in S^2 \) for the entropy dissipation argument to apply and to exclude this case.

Case 1(ii). The bound (4.5) holds, but the second condition of 1(i) is violated. And so using (4.3), \( \int_{W_j} g_j(v_*)d\omega \geq \frac{\delta}{6} \), where \( W_* = \{ v_* \in V'_\lambda \setminus S_{\delta/4} : \sigma_* < 10^{-3}d \} \). For \( v \in W_{j1} \) and \( v_* \in W_* \), notice that \( |v - v_*| \geq \frac{\delta}{2} \). Write \( W_* = A_1 \cup A_2 \cup A_3 \), with three disjoint subsets \( A_1, A_2, A_3 \), such that

\[
\inf_{A_1} g_j(v_*) \geq \sup_{A_2} g_j(v_*) \geq \inf_{A_3} g_j(v_*) \geq \sup_{A_3} g_j(v_*) \quad \text{and}
\]

\[
\int_{A_1} g_j(v_*)d\omega = \int_{A_2} g_j(v_*)d\omega = \int_{A_3} g_j(v_*)d\omega \geq \frac{\delta}{6}.
\]

Analogously split \( W_{j1} \) into three disjoint sets \( B_1, B_2, B_3 \) with the same properties. Denote by \( S(v, v_*) \) the subset of \( \omega \in S^2 \) such that \( v', v'_* \in V'_\lambda, \sigma' \geq \frac{\delta}{8} \) and \( \sigma'_* \geq \frac{\delta}{8} \). We shall discuss the case when \( \sup_{A_2} g_j(v_*) \leq \inf_{B_1} g_j(v) \) for an infinite sequence of \( j \)'s. The converse case is analogous after changing the roles of \( v \) and \( v_* \). There is a positive uniform bound from below \( C_\omega \) for the measure of \( S(v, v_*) \). Suppose 2 \( \int g_j(v_*)d\omega \geq \int_{A_1} g_j(v_*)d\omega \) where the first integral is taken over those \( v_* \in A_2 \) for which \( g_j g_j \geq 2g_jg_j \), for at least half of \( S(v, v_*) \). This cannot hold for infinitely many \( j \)'s since

\[
\frac{\eta}{3} \leq \int_{W_{j1}} g_j(v)dv \leq CG(x_j + y) \rightarrow 0, j \rightarrow \infty.
\]

So the converse holds for infinitely many \( j \)'s. Then \( g_j(v_*) \leq \sqrt{2}g_j(v') \) on at least \( \frac{1}{4} \)th of \( S(v, v_*) \). And so \( g_j(v_*) \leq \frac{4\sqrt{2}}{C_\omega} \int g_j(v')d\omega \) where the integral is
over the $\frac{1}{4}$th of $S(v,v_*)$. The Jacobian of the Carleman transformation of the gain term is uniformly bounded with respect to the relevant $v, v_*$, and $\omega$ in respectively $B_1, A_2$, and $S(v,v_*)$.

Then switch from $v_*$ to such $v'$ at a distance $\geq \frac{d}{\sigma}$ from the $\eta$-axis. Cylindrical symmetry can be applied for $v'$ to generate enough volumes in $V'(v,v', v'_*)$ and $V'_*(v,v', v'_*)$ for the entropy dissipation argument to apply, excluding this case when $j$ is large enough.

Case 2(i). The bound (4.6) holds, and $\int_W g_j(v) dv > \frac{\sigma}{6}$, where $W = \{v \in W_j; \sigma \geq 10^{-3}d\}$. Then denote by $\tilde{W}_j$ the image set of $W$ by rotation around the $\xi$-axis. Moreover, given $v$, by (4.4)

$$\int_{W_*,v} g_j(v_*) dv_* > \frac{d}{2},$$

where $W_*,v := \{v_*; v_* - v \geq d, g_j(v_*) > \frac{d}{2 |V'_\lambda|\frac{d}{10^{-3}d}}\}$. Taking $v \in \tilde{W}_j, v_* \in W_*,v$, and using rotation around the $\xi$-axis in $\tilde{W}_j$, generates volumes bounded from below for which $g_j(v'), g_j(v'_*)$ are uniformly bounded from above and for which the entropy dissipation argument applies, excluding this case when $j$ is large enough.

Case 2(ii). The bound (4.6) holds, and $\int_{W_j} g_j(v) dv > \frac{\sigma}{8}$, where $W_j = \{v \in W_j; \sigma < 10^{-3}d\}$. Then, either given $v$, by (4.4)

$$\int_{|v_* - v| \geq d, \sigma \geq 10^{-3}d} g_j(v_*) dv_* > \frac{d}{2},$$

For such $v \in W_j$, taking $v_*$ in the image set by rotation around the $\xi$-axis of $\{v_* \in V'_\lambda; v_* - v \geq d, \sigma \geq 10^{-3}d, g_j(v_*) > \frac{d}{8 |V'_\lambda|}\}$, and taking suitable $\omega \in S^2$, gives a setting where the entropy dissipation argument applies. Or otherwise

$$\int_{|v_* - v| \geq d, \sigma < 10^{-3}d} g_j(v_*) dv_* > \frac{d}{2},$$

and the argument of Case 1(ii) can be used. And so this type of concentration is excluded.

Case 3. The bound (4.7) holds. Denote by $\tilde{W}_{j3}$ the image set of $W_{j3}$ by rotation around the $\xi$-axis. Then $\int_{\tilde{W}_{j3}} g_j(v) dv > \frac{\sigma}{8}$. Taking $v \in \tilde{W}_{j3}$, suitable $v_* \in V'_\lambda \setminus S_\delta$ and $\omega \in S^2$, generates using (4.3), a setting where the entropy dissipation argument applies as in the earlier cases, thus excluding also this final possibility.

We conclude that $(g_j)$ is uniformly equiintegrable. It then follows for $y$ with
\[
\lim_{j \to \infty} G(y + x_j) = 0 \text{ from the weak } L^1\text{-compactness just proved and using Lemma 2.4, that there is a sequence } (M_j(v)) \text{ of Maxwellians such that }
\]
\[
\lim_{j \to \infty} \int | g(x_j + y, v) - M_j(v) | \, dv = 0.
\]
Moreover,
\[
\lim_{j \to \infty} \int (\xi, \xi^2, \xi v^2) M_j(v) \, dv = (c_1(\lambda, \mu), c_2(\lambda, \mu), c_3(\lambda, \mu)).
\]
Except in the case \( c_1 c_3 = c_2^2 \) and \( T_s = 0 \), this implies (for a subsequence) that \( \lim_{j \to \infty} \int | M_j(v) - M_-(v) | \, dv = 0 \) or \( \lim_{j \to \infty} \int | M_j(v) - M_+(v) | \, dv = 0 \).
It then remains to prove that
\[
\lim_{x \to \infty} \int | g(x, v) - M_-(v) | \, dv = 0
\]
in the first case, and that
\[
\lim_{x \to \infty} \int | g(x, v) - M_+(v) | \, dv = 0
\]
in the second case. We carry out the proof in the first case. Let
\[
0 < \epsilon < \min[\delta, 10^{-1} \int | M_-(v) - M_+(v) | \, dv, \ 10^{-1} \int_{V_\lambda \setminus S_0} M_-(v) \, dv] \quad (4.8)
\]
be given. Let us prove that for \( x \) large enough, \( \int | g(x, v) - M_-(v) | \, dv < 2\epsilon \), when we already know that there is \( j_0 \), such that
\[
\int | g(x_j + y, v) - M_-(v) | \, dv < \epsilon, \quad j \geq j_0.
\]
Let \( a_2 \) be such that
\[
\int | g(r, v) - g(s, v) | \, dv < \epsilon, \quad | r - s | < a_2.
\]
We have
\[
\int_{V_\lambda \setminus S_0} g(x_j + y, v) \, dv \geq \int_{V_\lambda \setminus S_0} M_-(v) \, dv
\]
\[
- \int_{V_\lambda \setminus S_0} g_j(x_j + y, v) - M_-(v) | \, dv \geq 10\epsilon - \epsilon = 9\epsilon, \quad j \geq j_0.
\]
And so,
\[ \int_{V_{\lambda}\setminus S_0} g(z,v)dv > 8\epsilon, \quad z \in [x_j + y - a_2, x_j + y + a_2], j \geq j_0. \]

Now \( \lim_{X \to +\infty} \int_X^{+\infty} G(x)dx = 0 \), and so given \( \eta > 0 \), there is \( X_1 > 0 \) such that \( \text{meas}\{z > X_1; G(z) > \eta\} < \frac{\eta}{2} \). So for \( j \geq j_0 \) there is \( z_j \in [x_j + y + \frac{2a_2}{n}, x_j + y + a_2] \) such that \( G(z_j) < \eta \). Here \( \eta > 0 \) has by the previous discussion been chosen small enough, so that
\[
\min\left( \int |g(z_j, v) - M_{-}(v)| dv, \int |g(z_j, v) - M_{+}(v)| dv \right) < \epsilon.
\]

But
\[
\int |g(z_j, v) - M_{+}(v)| dv \geq \int |M_{+}(v) - M_{-}(v)| dv
\]
\[-(\int |M_{-}(v) - g(x_j + y), v)| dv + \int |g(x_j + y, v) - g(z_j, v)| dv) > 8\epsilon.
\]

Hence
\[
\min\left( \int |g(z_j, v) - M_{-}(v)| dv, \int |g(z_j, v) - M_{+}(v)| dv \right) = \int |g(z_j, v) - M_{-}(v)| dv < \epsilon,
\]
\[
\int |g(z, v) - M_{-}(v)| dv < \int |g(z, v) - g(z_j, v)| dv
\]
\[+ \int |g(z_j, v) - M_{-}(v)| dv < 2\epsilon, \quad z \in [x_j + y, x_j + y + a_2].
\]

We can now repeat the above discussion from \( x_j + y + a_2 \) instead of \( x_j + y \), and in a finite number of iterations reach \( x_{j+1} + y \).

In the remaining case when \( c_1c_3 = c_2^2 \) and \( T_+ = 0 \), we replace \( \int |M_{-}(v) - M_{+}(v)| dv \) with \( \inf \int |M_{-}(v) - M_{\lambda,\mu}| dv \). Here the infimum is taken over the family \( \mathcal{F} \) of \( (\lambda,\mu) \)-truncated Maxwellians \( M_{\lambda,\mu} \) according to Lemma 2.2. Using (2.5) we choose \( (\lambda_0,\mu_0) \) so that the infimum in (4.8) is positive in this case. Then the above proof can be repeated in the case \( T_+ = 0 \), if \( M_{+} \) is replaced by relevant members \( M_{\lambda,\mu} \) from the family \( \mathcal{F} \). \( \square \)
5 A hydrodynamic limit in the slab.

This section is devoted to a proof of Theorem 2.7.
Proof of Theorem 2.7. Let \( 0 < \epsilon_j, j \in \mathbb{N} \), be a decreasing sequence with \( \sum j \epsilon_j < \infty \), and with \( f_{\epsilon_j} \) converging in weak* measure sense to a measure \( f \). Write \( f_{\epsilon_j} = f_j \). Set

\[
G_{\epsilon}(x) = \int b \chi(fJ \cdot f_{\epsilon_j} - f \cdot f_{\epsilon_j}) \log \frac{fJ \cdot f_{\epsilon_j}}{f \cdot f_{\epsilon_j}}(x, v, v*, \omega) dv d\omega d\omega
\]

The above hypotheses imply that

\[
\sum_{j=1}^{\infty} \int G_{\epsilon_j}(x) dx \leq C \sum j \epsilon_j < \infty.
\]

And so for a.e. \( x \),

\( \sum_j G_{\epsilon_j}(x) < \infty, \)

and in particular \( \lim_{j \to \infty} G_{\epsilon_j}(x) = 0 \). Moreover, given \( m \in \mathbb{N} \), in the complement \( I_m \) of some set of measure less than \( m^{-1} \) in \([-1, 1] \), \( G_{\epsilon_j} \) converges uniformly to 0 when \( j \) tends to infinity. Let \( \chi_m(x) \) be the characteristic function of \( I_m \). Let \( \chi_{\epsilon_j}(x, v) \) be the characteristic function (in \( x \)) of those \( x \in [-1, 1] \), for which \( \int_{V_{\lambda} \setminus S_{\lambda-1}} f_j(x, v) dv > n^{-1} \), multiplied with the characteristic function (in \( v \)) of \( V_{\lambda} \setminus S_{\lambda-1} \). We may take the sequence \( (f_j) \) so that for each \( m, n \in \mathbb{N} \), the sequence \( (f_j \chi_{\epsilon_j} \chi_m)_{j \in \mathbb{N}} \) converges in weak* measure sense. By a variant of the reasoning in Section 4, the sequence is also weakly compact in \( L^1((-1, 1) \times V_{\lambda}) \), and with a weak* measure limit \( \theta_m^m M_+ + \theta_+^m M_+ \). Here \( \theta_m^m, \theta_+^m \) are increasing as functions of \( m, n \) with limits \( \theta_-, \theta_+ \), and as functions of \( x \) they satisfy \( 0 \leq \theta_m^m(x), \theta_+^m(x), \theta_-^m(x) + \theta_+^m(x) \leq 1 \) with \( \theta_+ \equiv 0 \) in the case \( c_2 > c_1 c_3 \).

For test functions \( \phi \) with support in \( V_{\lambda} \setminus S_{\lambda-1} \),

\[
\left| \int f_j(1 - \chi_{\epsilon_j}) \phi dx dv \right| \leq 2 \| \phi \|_{\infty} n^{-1}.
\]

Also

\[
\int f_j(1 - \chi_m) dx dv \leq m^{-1} c_2 \frac{c_2}{\mu^2}.
\]

And so

\[
\int \phi f dx dv = \lim_{j \to \infty} \int f_j \phi dx dv = \lim_{j \to \infty} \int f_j(1 - \chi_m) \phi dx dv
\]
$$+ \lim_{j \to \infty} \int f_j (1 - \chi_{j_n}) \chi_m \phi dx dv + \lim_{j \to \infty} \int f_j \chi_{j_n} \chi_m \phi dx dv$$

$$= \int (\theta_\cdot M_- + \theta_\cdot M_+) \phi dx dv + O_{nm},$$

where $O_{nm}$ tends to zero when $n, m \to \infty$. And so

$$\int \phi f dx dv = \int (\theta_\cdot M_- + \theta_\cdot M_+) \phi dx dv.$$

By the same argument for any $\delta > 0$, for any test function $\phi$ and with $\chi$ the characteristic function of $V_\lambda \setminus S_\delta$,

$$\int \phi \chi f dx dv = \int (\theta_\cdot M_- + \theta_\cdot M_+) \chi \phi dx dv.$$

It follows that $f$ is composed of a singular measure on $[-1, 1] \times S_0$, together with a Lebesgue absolutely continuous measure with density $\theta_\cdot M_- + \theta_\cdot M_+$. Finally $\int \phi f dv$ is Lebesgue measurable in $x$ and

$$\int \xi (1, \xi, v^2) f dv = (c_1, c_2, c_3) (\lambda, \mu).$$
