ON THE CONNECTION BETWEEN SETS OF OPERATOR SYNTHESIS AND SETS OF SPECTRAL SYNTHESIS FOR LOCALLY COMPACT GROUPS

JEAN LUDWIG AND LYUDMILA TUROWSKA

We extend the results by Froelich and Spronk & Turowska on the connection between operator synthesis and spectral synthesis for $A(G)$ to second countable locally compact groups $G$. This gives us another proof that one-point subset of $G$ is a set of spectral synthesis and that any closed subgroup is a set of local spectral synthesis. Furthermore we show that “non-triangular” sets are strong operator Ditkin sets and we establish a connection between operator Ditkin sets and Ditkin sets. These results are applied to prove that any closed subgroup of $G$ is a local Ditkin set.

1. Introduction

In [A] Arveson discovered a connection between the invariant subspace theory and spectral synthesis. He defined (operator) synthesis for subspace lattices and proved the failure of operator synthesis by using the famous example of Schwartz on non-synthesizability of the two-sphere $S^2$ for $A(\mathbb{R}^3)$. In [F] Froelich made this connection more precise for separable abelian group. For $G$ a separable compact group this relation was obtained in [ST, Theorem 4.6]. We generalize these results to second countable locally compact groups (Theorems 4.3 and 4.10). We use the definition of sets of operator synthesis as defined in [ShT1]. We prove that a closed subset $E \subset G$ is set of local spectral synthesis for $A(G)$ if and only if the diagonal set $E^* = \{(s, t) \in G \times G \mid st^{-1} \in E\}$ is a set of operator synthesis with respect to Haar measure. We remark that if $A(G)$ has an (unbounded) approximate identity then any set of local spectral synthesis is a set of synthesis for $A(G)$ and any compact set of local spectral synthesis is globally spectral for any group $G$. We give a new proof that a one-point set is spectral and any closed subgroup of second countable group is a set of local spectral synthesis. Using operator synthesizability of sets of finite width we obtain certain example of sets of spectral synthesis. Operator-Ditkin sets have been defined in [ShT1]. In Section 5 we show first that “non-triangular” type sets are strong operator-Ditkin. The proof is inspired by [D]. For $G$ second countable group we prove that the diagonal set $E^* \subset G \times G$ is a strong operator-Ditkin set with respect to Haar measure then $E \subset G$ is a local Ditkin set for $A(G)$ and conversely, for any strong Ditkin set $E \subset G$, the set $E^*$ is operator-Ditkin with respect to Haar measure. As an application we obtain that any closed subgroup of a second countable group is a local Ditkin set. This result was known for neutral subgroups of arbitrary locally compact groups $G$ ([DD]) and amenable groups $G$ ([FKLS]).
2. Preliminaries and notations

Let $G$ be a locally compact $\sigma$-compact separable group with left Haar measure $m = dg$. Let $L^p(G)$, $p = 1, 2$, denote the space of $p$-integrable functions with norm $\| \cdot \|_p$ and let $C_c(G)$ denote the algebra of continuous compactly supported complex-valued functions on $G$. The convolution algebra $L^1(G)$ is an involutive algebra with involution defined by $f^*(s) = \Delta^{-1}(s)f(s^{-1})$, where $\Delta$ is the modulus of the group. Let $\Sigma$ be the set of all (equivalence classes of) continuous unitary representations $\pi$ of $G$ in Hilbert spaces $H_\pi$. For $f \in L^1(G)$, $\pi \in \Sigma$, we put $\pi(f) = \int_G f(g)\pi(g)dg \in B(H_\pi)$ with the integral converging in the strong operator topology, and then

$$\|f\|_\Sigma = \sup_{\pi \in \Sigma} \|\pi(f)\|,$$

where $\| \cdot \|$ is the operator norm in $B(H_\pi)$.

The enveloping $C^*$-algebra $C^*(G)$ of $G$ is the completion of $L^1(G)$ with respect to $\| \cdot \|_\Sigma$. Let $\lambda : G \to B(L_2(G))$ be the left regular representation given by $\lambda(s)f(g) = f(s^{-1}g)$. We denote by $C_r^*(G)$ the reduced $C^*$-algebra of $G$, that is the $C^*$-algebra generated by operators $\lambda(f) \in B(L_2(G))$, $f \in L^1(G)$, and by $VN(G)$ the von Neumann algebra of $G$, that is

$$VN(G) = \overline{\text{span}}_{\text{WOT}} \{\lambda(g) : g \in G\} = C_r^*(G) \subset B(L_2(G)).$$

The Fourier-Stieltjes algebra, $B(G)$, is the set of all coefficients $s \mapsto \pi_{\xi, \eta}(s) = (\pi(s)\xi, \eta)$, where $\pi \in \Sigma$, $\xi, \eta \in H_\pi$, of unitary representations of $G$, as defined by Eymard, [E]. $B(G)$ is a Banach algebra with respect to the norm

$$\|u\| = \inf \{\|\xi\| \|\eta\| : u = \pi_{\xi, \eta}\}.$$

Note that $B(G) \simeq C^*(G)^*$.

The Fourier algebra, $A(G)$, is the family of functions $s \mapsto (\lambda(s)\xi, \eta) = \check{\eta} \ast \xi$, $\xi, \eta \in L_2(G)$, $\check{\xi}(s) = \xi(s^{-1})$. $A(G)$ is identified with the predual $VN(G)^*$ via $(\lambda(s)\xi, \eta), T = (T\xi, \eta)$, and thus is a normed algebra with the norm denoted by $\| \cdot \|_A$. It is known that for $u \in A(G)$ there exist even $\xi, \eta \in L_2(G)$ such that $u = \check{\eta} \ast \xi$ and $\|u\|_A = \|\xi\|_2 \|\eta\|_2$.

Furthermore, $A(G)$ is a closed ideal in $B(G)$.

Since $A(G)$ is the predual of the von Neumann algebra $VN(G)$, $A(G)$ possesses a structure of operator space and one can define a notion of completely bounded multipliers, $M_{cb}A(G)$, for $A(G)$. For the theory of operator space and completely bounded maps we refer the reader to [EfR, BS0, S]. A complex-valued function $u : G \to \mathbb{C}$ is a completely bounded multiplier if it is a multiplier, i.e. $uA(G) \subset A(G)$, and is completely bounded as a linear map on $A(G)$. We have $A(G) \subset B(G) \subset M_{cb}A(G)$ and, for $u \in A(G)$, $\|u\|_{cb} \leq \|u\|_A$, where $\| \cdot \|_{cb}$ is the completely bounded norm (see [S, Corollary 2.3.3]). We will use here a characterization of $M_{cb}A(G)$ obtained by N.Spronk in [S] as formulated in Theorem 3.1.

3. Spectral and operator synthesis

Let $A$ be a semisimple, regular, commutative Banach algebra with $X_A$ as spectrum; for any $a \in A$ we shall denote then by $\hat{a} \in C_0(X_A)$ its Gelfand transform. Let also $E \subset X_A$ be a closed subset. We then denote by

$$I_A(E) = \{a \in A \mid \hat{a}^{-1}(0) \text{ contains } E\},$$

$$J_A^0(E) = \{a \in A \mid \hat{a}^{-1}(0) \text{ contains a neighborhood of } E\} \text{ and } J_A(E) = \overline{J_A^0(E)}.$$
It is known that $I_A(E)$ and $J_A(E)$ are the largest and the smallest closed ideals with $E$ as hull, i.e., if $I$ is a closed ideal such that $\{x \in X_A : f(x) = 0 \text{ for all } f \in I\} = E$ then
$$J_A(E) \subset I \subset I_A(E).$$

Let $I_A^\dagger(E)$ denote the set of all compactly supported functions $f \in I_A(E)$. We say that $E$ is a set of spectral synthesis (local spectral synthesis) for $A$ if $J_A(E) = I_A(E)$ ($I_A^\dagger(E) \subset J_A(E)$).

Let $A^*$ be the dual of $A$. For $a \in A$ we set $\text{supp}(a) = \{x \in X_A : \hat{a}(x) \neq 0\}$ and $\text{null}(a) = \{x \in X_A : \hat{a}(x) = 0\}$. For $\tau \in A^*$ and $a \in A$ define $a\tau$ in $A^*$ by $a\tau(b) = \tau(ab)$ and define the support of $\tau$ by
$$\text{supp}(\tau) = \{x \in X_A : a\tau \neq 0 \text{ whenever } a(x) \neq 0\}.$$ Then, for a closed set $E \subset X_A$
$$J_A(E) = \{\tau \in A^* : \text{supp}(\tau) \subset E\}$$ and $E$ is spectral for $A$ if and only if $\tau(a) = 0$ for any $a \in A$ and $\tau \in A^*$ such that $\text{supp}(\tau) \subset E \subset \text{null}(a)$.

The algebra $A(G)$ is a semi-simple abelian regular Banach algebras with spectrum $G$. In what follows we write $I_A(E)$ for $I_{A(G)}(E)$, $J_A(E)$ for $J_{A(G)}(E)$, and $\text{supp}_V T$ for $\text{supp}(T)$ if $T \in V N(G) = (A(G))^{**}$.

Now we recall some definitions and important facts on operator synthesis following [A, ShT1]. To make use of the results from [A, ShT1] we will assume in the rest of the paper that $\hat{G}$ is a second countable locally compact group or s.c.l.c group for short, and therefore is metrizable by [HRI, 8.3].

A subset $E \subset G \times G$ is called marginally null (with respect to $m \times m$) if $E \subset (M \times G) \cup (G \times N)$ and $m(M) = m(N) = 0$. Two subsets $E_1$, $E_2$ are marginally equivalent ($E_1 \sim^M E_2$ or simply $E_1 \equiv E_2$) if their symmetric difference is marginally null. Furthermore, $E_1 \subset^M E_2$ means that $E_1 \setminus E_2$ is marginally null, a property holds marginally almost everywhere if it holds everywhere apart of a marginally null set, and so on.

Following [ErKSh] we define a pseudo-topology on $G$. We call a subset $E$ a pseudo-open if it is marginally equivalent to a countable union of measurable rectangles $A \times B$. The complements of pseudo-open sets are pseudo-closed sets.

Set $T(G) = L^2(G) \hat{\otimes} L^2(G)$, where $\hat{\otimes}$ denotes the projective tensor product. Note that in [ShT1] the notation $\Gamma(G, G)$ is used instead of $T(G)$. Every $\Psi \in T(G)$ can be identified with a function $\Psi : G \times G \to \mathbb{C}$ which admits a representation

\begin{equation}
\Psi(x, y) = \sum_{n=1}^\infty f_n(x)g_n(y)
\end{equation}

where $f_n \in L^2(G)$, $g_n \in L^2(G)$ and $\sum_{n=1}^\infty \|f_n\|_2 \cdot \|g_n\|_2 < \infty$. Such a representation defines a function marginally almost everywhere (m.a.e.), so two functions in $T(G)$ which coincides m.a.e. are identified. The $L^2(G) \hat{\otimes} L^2(G)$-norm of $\Psi$ is
$$\|\Psi\|_{T(G)} = \inf \{\sum_{n=1}^\infty \|f_n\|_2 \cdot \|g_n\|_2 : \Psi = \sum_{n=1}^\infty f_n \otimes g_n\}.$$

Note that a simple renormalization shows that each $\Psi \in T(G)$ admits a representation (3.1) such that $\sum_{n=1}^\infty \|f_n\|_2^2 \cdot \sum_{n=1}^\infty \|g_n\|_2^2 < \infty$ and the norm $\|\Psi\|_{T(G)}$ can be taken as the
square root of the infimum of \( \sum_{n=1}^{\infty} \| f_n \|^2 \cdot \sum_{n=1}^{\infty} \| g_n \|^2 \) over all such representations. By \[ \text{ErKSh} \] any \( \Psi \in T(G) \) is pseudo-continuous. Thus if \( \Psi \) vanishes (m.a.e.) on \( K \subset G \) it vanishes on a pseudo-closed set. For \( \mathcal{F} \subset T(G) \), the null set, null \( \mathcal{F} \), is defined to be the largest pseudo-closed set such that each function \( F \in \mathcal{F} \) vanishes on it. For a pseudo-closed set \( E \subset G \times G \), let

\[
\Phi(E) = \{ w \in T(G) : w = 0 \text{ m.a.e. on } E \},
\]

\[
\Phi_0(E) = \{ w \in T(G) : w = 0 \text{ on a pseudo-neighbourhood of } E \}.
\]

The spaces \( \Phi(E), \Phi_0(E) \) are \( L^\infty(G) \times L^\infty(G) \)-bimodules: if \( f, g \in L^\infty(G) \) and \( w \in \Phi(E) \) (\( w \in \Phi_0(E) \)) then \( f(x)g(y)w(x,y) \in \Phi(E) \) (\( f(x)g(y)w(x,y) \in \Phi_0(E) \) respectively). Moreover, \( \Phi(E) \) and \( \Phi_0(E) \) are the largest and the smallest \( L^\infty(G) \times L^\infty(G) \)-invariant subspaces of \( T(G) \) whose null set is \( E \).

A subset \( E \subset G \times G \) is called a set of (operator) synthesis or synthetic with respect to \( m \) if \( \Phi(E) = \Phi_0(E) \).

It is known that \( B(L_2(G)) \simeq T(G)^* \) (see \[ \text{A} \]). The duality is given by

\[
\langle T, \Psi \rangle = \sum_{n=1}^{\infty} \langle T f_n, g_n \rangle,
\]

for \( T \in B(L_2(G)) \) and \( \Psi = \sum_{n=1}^{\infty} f_n \otimes g_n \in T(G) \).

Let \( P_U \) denote the multiplication operators by the characteristic functions of a subset \( U \subset G \). We say that \( T \in B(L_2(G)) \) is supported in \( E \subset G \times G \) (or \( E \) supports \( T \)) if \( P_VTP_U = 0 \) for each pair of Borel sets \( U \subset G, V \subset G \) such that \( (U \times V) \cap E = \emptyset \). Then there exists the smallest (up to a marginally null set) pseudo-closed set, \( \text{supp}T \), which supports \( T \). We write \( \text{supp}T \subset E \) if \( T \) is supported by \( E \). In the seminal paper \[ \text{A} \] Arveson defined a support in a similar way but using closed sets instead of pseudo-closed. This closed support, \( \text{supp}_\text{cl}T \), can be strictly larger than \( \text{supp}T \). Then \( E \) is a set of operator synthesis if \( \langle T, w \rangle = 0 \) for any \( T \in B(L_2(G)) \) and \( w \in T(G) \) with \( \text{supp}T \subset E \subset \text{null} w \) (the inclusions up to a marginally null set).

We consider also the space \( V^\infty(G) \) of all (marginal equivalence classes of) functions \( \Psi(x,y) \) that can be written in the form (3.1) with \( f_n \in L^\infty(G), g_n \in L^\infty(G) \) and

\[
\sum_{n=1}^{\infty} |f_n(x)|^2 \leq C, \quad x \in G, \quad \sum_{n=1}^{\infty} |g_n(y)|^2 \leq C, \quad y \in G,
\]

and for such \( \Psi \) we have

\[
||\Psi||_{V^\infty} = \inf\{||\sum_{n=1}^{\infty} |f_n|^2||_{1/2} : \sum_{n=1}^{\infty} |g_n|^2||_{1/2} : \Psi = \sum_{n=1}^{\infty} f_n \otimes g_n \}.
\]

In tensor notations \( V^\infty(G) = L^\infty(G) \otimes^w L^\infty(G) \), the weak*-Haagerup tensor product ([BSm]).

Let \( V^\text{inv}_{\text{inv}}(G) = \{ w \in V^\infty(G) : w(sr, tr) = w(s,t) \text{ for all } r \in G \} \) and m.a.e. \( (s,t) \in G \times G \).

In [S] Spronk found a connection between \( V^\text{inv}_{\text{inv}}(G) \) and the algebra \( M_{cb}A(G) \) of completely bounded multipliers of \( A(G) \). For a function \( u : G \to \mathbb{C} \) and \( s, t \in G \) define

\[
(Nu)(t,s) = u(ts^{-1}).
\]

**Theorem 3.1.** [S] The map \( u \mapsto Nu \) is a complete isometry from \( M_{cb}A(G) \) onto \( V^\text{inv}_{\text{inv}}(G) \).
4. Spectral synthesis and operator synthesis

In this section we will prove our main result establishing a connection between operator synthesis and spectral synthesis for $A(G)$, where $G$ is a second countable locally compact group. The proofs are inspired by the proof of [ST, Theorem 4.6].

The Banach space $B(L_2(G))$ is a left $V^\infty(G)$-module with the action defined for $w = \sum_{i=1}^\infty \varphi_i \otimes \psi_i \in V^\infty(G)$ and $T \in B(L_2(G))$ by

$$w \cdot T = \sum_{i=1}^\infty M_{\psi_i}T M_{\varphi_i},$$

where the partial sums converge strongly. The operator $T \mapsto \sum_{i=1}^\infty M_{\psi_i}T M_{\varphi_i}$ we will also denote by $\Delta_w$.

For a closed subset $E \subset G$ we set

$$E^* = \{(s,t) \in G \times G \mid st^{-1} \in E\}.$$

Lemma 4.1. Let $S \in VN(G)$. Then

$$\text{supp}(S) \subset \{\text{supp}_{VN} S\}^*.$$

Proof. Let $U, V$ be closed subsets of $G$ such that $(U \times V) \cap \{\text{supp}_{VN}(S)\}^* = \emptyset$. Then there exists an open neighborhood, $W$, of $\{\text{supp}_{VN}(S)\}^*$ such that $(U \times V) \cap W = \emptyset$. Take $f$ and $g$ in $L_2(G)$ such that $\text{supp}(f) \subset U$, $\text{supp}(g) \subset V$. For $u = \langle \lambda(\cdot)f, g \rangle$, we have $\langle Sf, g \rangle = \langle u\rangle$. Moreover, $\text{supp}(u) \subset UV^{-1}$ and $\text{supp}(u) \cap \text{supp}_{VN}S \subset UV^{-1} \cap \text{supp}_{VN}S = \emptyset$. Thus $0 = \langle S, u \rangle = \langle Sf, g \rangle$. As $f$ and $g$ are chosen arbitrarily, $P_{V}SP_{U} = 0$. By the regularity of $m$, the last holds for any Borel sets $U, V$ giving the statement. $\square$

Remark 4.2. Let $H$ be a closed subgroup of $G$. Then

$$H^* = \{(s,t) \in G \times G : st^{-1} \in H\} = \{(s,t) \in G \times G : Hs = Ht\}$$

$$= \{(s,t) \in G \times G : f(t) = f(s)\},$$

where $f : G \to H$ is a continuous mapping defined by $f(t) = Ht$.

Assume $\text{supp}_{VN}(S) \subset H$. By Lemma 4.1, $\text{supp}(S) \subset H^*$. As for any Borel set $\Delta \subset H \setminus G$ and $\alpha = f^{-1}(\Delta)$, we have $(\alpha \circ \alpha) \cap H^* = \emptyset$, it gives $P_{\alpha^c}SP_{\alpha} = 0$. Since this is true for any $\Delta$ we have also $P_{\alpha}SP_{\alpha} = 0$ implying that $P_{\alpha}S = SP_{\alpha}$ and hence $S$ belongs to the commutant $B'$ of the von Neumann algebra $B \subseteq L^\infty(G)$ which are constant on the right cosets.

Theorem 4.3. Let $G$ be a s.c.l.c. group and $E \subset G$ be a closed subset. If $E^*$ is synthetic with respect to $m$ then $E$ is a set of local synthesis for $A(G)$.

Proof. Assume that $E^*$ is synthetic with respect to $m$. Let $u \in I_3^*(E)$ and $S \in VN(G)$, $\text{supp}_{VN}(S) \subset E$. By Theorem 3.1, $Nu \in V^\infty(G)$. Moreover, $uT = \Delta_{Nu}T$ for any $T \in VN(G)$.

In fact, if $Nu(s,t) = \sum_i \varphi_i(t)\psi_i(s)$, then

$$\Delta_{Nu}\lambda(s)f(t) = \sum_i M_{\psi_i}\lambda(s)M_{\varphi_i}f(t) = \sum_i \varphi_i(t)\psi_i(s^{-1}t)f(s^{-1}t) = Nu(t,s^{-1}t)f(s^{-1}t) = u(s)\lambda(s)f(t)$$
for any \( f \in L^2(G) \) and \( s \in G \). The operator \( \Delta_{Nu} \) is weakly-continuous. In fact, if \( S_k \to 0 \) weakly, \( ||S_k|| \leq C \) for some constant \( C \) and

\[
|\langle \Delta_{Nu}(S_k)f, g \rangle| \leq \sum_{i=1}^{n} |\langle S_k \psi_i f, \tilde{\varphi}_i g \rangle| + \sum_{i=n+1}^{\infty} |\langle S_k \psi_i f, \tilde{\varphi}_i g \rangle| \\
\leq \sum_{i=1}^{n} |\langle S_k \psi_i f, \tilde{\varphi}_i g \rangle| + ||S_k|| \left( \sum_{i=n+1}^{\infty} ||\psi_i f||^2 \right)^{1/2} \left( \sum_{i=n+1}^{\infty} ||\varphi_i g||^2 \right)^{1/2} \\
= \sum_{i=1}^{n} |\langle S_k \psi_i f, \tilde{\varphi}_i g \rangle| + C \left( \int_{G} \sum_{i=n+1}^{\infty} |\psi_i(t)f(t)|^2 dt \right)^{1/2} \left( \int_{G} \sum_{i=n+1}^{\infty} |\varphi_i(t)g(t)|^2 dt \right)^{1/2} .
\]

For given \( \varepsilon > 0 \), by Lebesgue’s theorem, there exists \( n \) such that the second summand is less than \( \varepsilon \) and then, as \( S_k \to 0 \) weakly, there exists \( K \) such that the first summand is less than \( \varepsilon \) for any \( k \geq K \). Therefore (4.2) holds for any \( T \in V N(G) \).

Clearly, since \( u \in I_A(E) \), \( Nu \) vanishes on \( E^* \). By Lemma 4.1, we also have that \( \text{supp}(S) \subset \{ \text{supp}_{V N}(S) \}^* \subset E^* \). Therefore, for each \( w \in T(G) \),

\[
\langle \Delta_{Nu}S, w \rangle = \langle S, (Nu)w \rangle = 0
\]

so that \( uS = \Delta_{Nu}S = 0 \).

From the regularity of \( A(G) \) it follows that there exists a compactly supported function \( v \in A(G) \) such that \( v = 1 \) on the support of \( u \). Thus

\[
\langle S, u \rangle = \langle S, vu \rangle = \langle uS, v \rangle = 0.
\]

\( \square \)

It is easy to see that the condition for \( E \) to be a set of local synthesis for \( A(G) \) is equivalent to the condition \( uS = 0 \) for any \( u \in A(G) \) and \( S \in V N(G) \) such that \( \text{supp}_{V N}(S) \subset E \subset \text{null } u \). If \( G \) is amenable then we have the implication

\[
(4.3) \quad uT = 0 \Rightarrow \langle T, u \rangle = 0,
\]

guaranteed by the existence of a bounded approximate identity and any set of local synthesis is a set of synthesis. Certainly the assumption of boundedness of the identity is superfluous, and the statement holds even for \( G \) such that \( A(G) \) has an unbounded approximate identity. So that we have

**Corollary 4.4.** Let \( G \) be a s.c.l.c. group such that \( A(G) \) has an (unbounded) approximate identity and let \( E \) be a closed subset of \( G \). If \( E^* \) is a set of operator synthesis with respect to \( m \) then \( E \) is a set of spectral synthesis.

It is not known whether an approximate identity exists for any locally compact group \( G \). Unbounded approximate identities which are completely bounded as multipliers of the Fourier algebra \( A(G) \) were studied in [CaH, Ca, CoH]. Those exist for a number of groups like the general Lorentz group \( SO_0(n, 1) \), its closed subgroups, in particular, the free group \( \mathbb{F}_n \) on \( n \) generators, extensions of \( SO_0(n, 1) \) by a finite group, in particular, \( SL(2, \mathbb{R}) \), \( SL(2, \mathbb{C}) \), \( SL(2, \mathbb{H}) \), and weakly-amenable groups.

The property (4.3) of an operator \( T \in V N(G) \) was discussed in [E] and called there by the property \((H)\). In particular, it was shown that any \( T \) supported in a compact set
$E$ possesses this property. Thus any compact set of local synthesis is a set of spectral synthesis.

**Corollary 4.5.** Let $E$ be a compact subset of $G$. If $E^*$ is a set of synthesis with respect to $m$ then $E$ is a set of spectral synthesis.

It is not known whether there exists $T \in VN(G)$ which does not satisfy $(4.3)$. The next statement was proved by Eymard for arbitrary locally compact groups $G$, $[E]$, using more complicated arguments of the theory of distributions on $G$.

**Corollary 4.6.** Let $s$ be an element of the s.c.l.c. group $G$. Then $\{s\}$ is a set of spectral synthesis.

**Proof.** It is enough to prove the statement for $E = \{e\}$, where $e$ is the identity element in $G$. In this case $E^* = \{(s, s) : s \in G\}$. That $E^*$ is a set of operator synthesis follows e.g. from [ShT1, Theorem 4.8], but it can be easily seen also using the following simple arguments.

Let $T \in B(L_2(G))$ and $\text{supp}(T) \subset E^*$. It follows from Remark 4.2 that $T$ is the multiplication operator by some function $a \in L^{\infty}(G, m)$. Let now $F = \sum_{i=1}^{\infty} f_i \otimes g_i \in \Phi(E^*)$. Then

$$\langle T, F \rangle = \sum_{i=1}^{\infty} (Tg_i, \tilde{f}_i) = \sum_{i=1}^{\infty} (ag_i, \tilde{f}_i) = \int_G a(r) F(r, r) dr = 0,$$

and therefore $E^*$ is a set of synthesis with respect to $m$. By Corollary 4.5, $E$ is a set of spectral synthesis. $\square$

We also have another proof in the case of s.c.l.c. groups of the following statement proved by Herz, [He, Theorem 2].

**Corollary 4.7.** Any closed subgroup $H$ of $G$ is a set of local spectral synthesis.

**Proof.** We have $H^* = \{(s, t) \in G \times G : st^{-1} \in H\} = \{(s, t) \in G \times G : H s = H t\} = \{(s, t) \in G \times G : f(t) = f(s)\}$, where $f : G \rightarrow H \setminus G$ is a continuous function defined by $f(t) = H t$. By [ShT1, Theorem 4.8], $H^*$ is a set of operator synthesis and the statement now follows from Theorem 4.3. $\square$

**Remark 4.8.** By Corollaries 4.4, 4.5, any compact subgroup $H$ is spectral for $A(G)$ and any closed subgroup is spectral for $A(G)$ if $A(G)$ has an approximate identity. That any closed subgroup of a locally compact group $G$ is a set of spectral synthesis was shown by Takesaki and Tatsuuma, [TT, Theorem 3], using the Mackey imprimitivity theorem and the result mentioned in Remark 4.2 proved by a different method.

**Example 4.9.** Let $R$ be an ordered s.c.l.c. group and $\Delta : G \rightarrow R$ be a continuous homomorphism. Take a finite intersection of intervals $\cap_{k-1}^{m}[\alpha_k, \beta_k]$ in $R$ and set $E = \Delta^{-1}(\cap_{k=1}^{m}[\alpha_k, \beta_k])$. Then

$$E^* = \{(s, t) : \alpha_k \leq \Delta(st^{-1}) \leq \beta_k, k = 1, \ldots, m\} = \{(s, t) : \alpha_k \Delta(t) \leq \Delta(s) \leq \beta_k \Delta(t), k = 1, \ldots, m\} = \{(s, t) : f_k^i(t) \leq g_k^i(s), i = 1, 2, k = 1, \ldots, m\},$$

where $f_k^i(t) = \alpha_k \Delta(t)$, $f_k^i(t) = (\Delta(t))^{-1}$, $g_k^i(s) = \Delta(s)$, $g_k^i(s) = (\Delta(s))^{-1}$, $\beta_k$. By [ShT1, Theorem 4.8], $E^*$ is a set of operator synthesis with respect to the Haar measure on $G$. Therefore $E$ is a set of spectral synthesis by Theorem 4.3.
Our next aim is to prove a converse to the statement of Theorem 4.3. The Banach space \( T(G) \) is an \( L^1(G) \)-module with the action defined by

\[
f \odot w(s, t) = \int_G f(r) \Delta^{1/2}(r) w(sr, tr) \, dr, \quad f \in L^1(G), w \in T(G),
\]

where \( \Delta \) is the modular function of \( G \). We have \( \|f \odot w\|_{T(G)} \leq \|f\|_1 \cdot \|w\|_{T(G)} \). Moreover, \( e_a \odot w \to w \) for any bounded approximate identity \( \{e_a\} \) in \( L^1(G) \) (see [HRI, 32.22, 32.33] and [ST, p.365]).

Let us define another action by compactly supported \( L^1(G) \)-functions \( f \):

\[
f \cdot w(s, t) = \int_G f(r) w(sr, tr) \, dr, \quad w \in T(G).
\]

Then \( f \odot w = f \Delta^{1/2} \cdot w \).

We observe that by the estimate (4.4) below, the integral \( \int_G f(r) w(sr, tr) \, dr, w \in T(G), s, t \in G \), converges also if \( f \in L^\infty(G) \) and so defines a mapping \( (s, t) \to f \cdot w(s, t) := \int_G f(r) w(sr, tr) \, dr \).

**Theorem 4.10.** Let \( G \) be a s.c.l.c. group. If a closed subset \( E \subset G \) is a set of local spectral synthesis for \( A(G) \) then \( E^\ast \) is synthetic with respect to Haar measure.

**Proof.** It is sufficient to show that \( w \cdot T = 0 \) for \( T \in B(L_2(G)) \) and \( w \in V^\infty(G) \) such that \( \text{supp}(T) \subset E^\ast \subset \text{null} \ w \) ([ShT2, Proposition 5.3]).

As \( G \) is second countable the group \( G \) is \( \sigma \)-compact and therefore there exist compact sets \( K_n \) such that \( K_n \subset K_{n+1} \) and \( \bigcup_{n=1}^\infty K_n = G \). Then clearly, \( M_{x_{K_n}} T M_{x_{K_{n+1}}} \to T \) strongly. Therefore we can restrict ourselves to a compactly supported operator \( T \), i.e. \( \text{supp}(T) \subset M \times M \) for a compact set \( M \subset G \), and compactly supported \( w \in V^\infty(G) \). Note that in this case \( w \in T(G) \).

Let \( \hat{G} \) denote the set of (equivalence classes of) irreducible continuous unitary representations of \( G \). For \( \pi \in \hat{G} \) let \( H_\pi \) denote the representation space of \( \pi \). Fix a basis \( \{e_j\} \) in \( H_\pi \) and denote by \( u_{k_j}^\pi \) the matrix coefficients of \( \pi \), i.e. \( u_{k_j}^\pi(s) = (\pi(s)e_k, e_j) \).

For (a compactly supported) \( w = \sum_{i=1}^\infty \varphi_i \otimes \psi_i \in T(G) \) and \( \pi \in \hat{G} \) consider now the following operator-valued function

\[
w^\pi(s, t) = \int_G w(sr, tr) \pi(r) \, dr.
\]
The integral is well-defined as a Bochner integral. In fact, for each \( s, t \in G \), applying Cauchy-Schwarz’s inequality, we obtain

\[
(4.4) \quad \int_G |w(sr, tr)| dr \leq \int_G \left( \sum_{i=1}^{\infty} |\varphi_i(sr)|^2 \right)^{1/2} \left( \sum_{i=1}^{\infty} |\psi_i(tr)|^2 \right)^{1/2} \, dr
\]

\[
\leq \left( \sum_{i=1}^{\infty} \int_G |\varphi_i(sr)|^2 dr \right)^{1/2} \left( \sum_{i=1}^{\infty} |\psi_i(tr)|^2 \right)^{1/2}
\]

\[
= \left( \sum_{i=1}^{\infty} ||\varphi_i||_2^2 \right)^{1/2} \left( \sum_{i=1}^{\infty} ||\psi_i||_2^2 \right)^{1/2} < \infty.
\]

Set \( \tilde{w}^\pi(s, t) = \pi(s) w^\pi(s, t) \) and

\[
(4.5) \quad w_k^{\pi}(s, t) = (w^\pi(s, t)e_k, e_j) = u_k^{\pi} \cdot w(s, t), \quad \tilde{w}_k^{\pi}(s, t) = (\tilde{w}^\pi(s, t)e_k, e_j).
\]

If \( w \in \Phi(E^*) \) then \( w(sr, tr) \) vanishes m.a.e. on \( E^* \) for all \( r \), and therefore \( w^\pi(s, t), \tilde{w}^\pi(s, t), w_k^{\pi}(s, t) \) and \( \tilde{w}_k^{\pi}(s, t) \) vanish on \( E^* \).

We have the following expression for \( w_k^{\pi} \) and \( \tilde{w}_k^{\pi} \):

\[
\tilde{w}_k^{\pi}(s, t) = \int_G w(sr, tr)(\pi(sr)e_k, e_j) \, dr = \int_G w(r, ts^{-1}r)(\pi(r)e_k, e_j) \, dr
\]

\[
= \int_G w(r, ts^{-1}r)u_k^{\pi}(r) \, dr.
\]

In particular, if \( w = f \otimes g \in T(G) \), then

\[
(4.6) \quad \tilde{w}_k^{\pi}(s, t) = \int_G f(r)u_k^{\pi}(r)g(ts^{-1}r) \, dr = N(fu_k^{\pi} \ast \tilde{g})(s, t).
\]

Furthermore

\[
w_k^{\pi}(s, t) = \int_G w(sr, tr)(\pi(sr)e_k, e_j) \, dr = \int_G w(r, ts^{-1}r)(\pi(s^{-1}r)e_k, e_j) \, dr
\]

\[
= \int_G w(r, ts^{-1}r)(\pi(r)e_k, \pi(s)e_j) \, dr
\]

\[
= \sum_l \int_G w(r, ts^{-1}r)(\pi(r)e_k, e_l)(e_l, \pi(s)e_j) \, dr
\]

\[
= \sum_l u_l^{\pi}(s) \int_G w(r, ts^{-1}r)u_k^{\pi}(r) \, dr = \sum_l u_l^{\pi}(s)\tilde{w}_l^{\pi}(s, t).
\]

We state first that \( \tilde{w}_k^{\pi}(s, t) \in V^\infty(G) \). Indeed, if \( w = f \otimes g \in T(G) \), then by (4.6) \( \tilde{w}_k^{\pi} = N(fu_k^{\pi} \ast \tilde{g}) \) and and therefore, since \( fu_k^{\pi} \ast \tilde{g} \in A(G) \), \( \tilde{w}_k^{\pi} \in V^\infty(G) \), by Theorem 3.1. Moreover,

\[
||\tilde{w}_k^{\pi}(s, t)||_{V^\infty} \leq ||fu_k^{\pi}||_{L^2}||g||_2 \leq ||f||_{L^2}||g||_2,
\]

9
so that the linear operator \( w \mapsto \hat{w}_{kj}^\pi \in V^\infty(G) \) defined on elementary tensors extends to a bounded operator \( T(G) \to V^\infty(G) \). Thus \( \hat{w}_{kj}^\pi \in V^\infty(G) \) for any \( w \in T(G) \).

Next we show that \( w_{kj}^\pi \in V^\infty(G) \). For \( T \in B(L^2(G)) \) and \( w = f \otimes g \in T(G) \) such that \( \|w\| = \|f\|_2 \|g\|_2 \), define \( w_{kj}^\pi \cdot T \) by

\[
(4.8) \quad \langle w_{kj}^\pi \cdot T, \Psi \rangle = \sum_l \langle \hat{w}_{kl}^\pi \cdot T, u_{lj}^\pi(s) \Psi(s,t) \rangle, \quad \Psi \in T(G).
\]

This formula makes sense. In fact, if \( \Psi = \sum_{i=1}^{\infty} f_i \otimes g_i \), such that \( \|\Psi\|_{T(G)}^2 = \sum_{i=1}^{\infty} \|f_i\|^2 \sum_{i=1}^{\infty} \|g_i\|^2 \), we have

\[
\left| \sum_l \langle \hat{w}_{kl}^\pi \cdot T, u_{lj}^\pi \Psi \rangle \right|^2 \leq \left( \sum_l \|\hat{w}_{kl}^\pi \cdot T\|^2 \right) \left( \sum_l \|u_{lj}^\pi \Psi\|^2_{T(G)} \right) \leq \|T\|^2 \left( \sum_l \|fu_{kl}^\pi\|^2 \|g\|^2 \right) \left( \sum_l \|u_{lj}^\pi f_i\|^2 \right) \cdot \sum_{i=1}^{\infty} \|g_i\|^2 \leq \|T\|^2 \|w\|^2_{T(G)} \|\Psi\|^2_{T(G)},
\]

the last equality follows from

\[
\sum_l \|fu_{kl}^\pi\|^2 = \sum_l \int_G |f(t)|^2 \sum_l |(\tau(t)e_k, e_i)|^2 dt = \int_G |f(t)|^2 \sum_l |(\tau(t)e_k)|^2 dt = \int_G |f(t)|^2 dt = \|f\|^2_2.
\]

Thus the operator \( w_{kj}^\pi \cdot T \) is well-defined for \( w = f \otimes g \) and since \( \|w_{kj}^\pi \cdot T\| \leq \|T\| \|w\|_{T(G)} \) for elementary tensors \( w \), the definition \( w_{kj}^\pi \cdot T \) makes sense for any \( w \in T(G) \) and

\[
(4.9) \quad \left| \sum_l \langle \hat{w}_{kl}^\pi \cdot T, u_{lj}^\pi \Psi \rangle \right|^2 \leq \|T\|^2 \|w\|^2_{T(G)} \|\Psi\|^2_{T(G)}
\]

for any \( \Psi \in T(G) \). Clearly, \( T \mapsto w_{kj}^\pi \cdot T \) is thus a bounded \( L^\infty(G) \)-bimodule map on \( B(L^2(G)) \) and hence by [Sm, 2.1] is completely bounded. Then by [BSm, 4.2], it is of the form \( \omega \cdot T \) for \( \omega \in V^\infty(G) \) and therefore \( w_{kj}^\pi \) is its m.a.e.

For \( \hat{w}^\pi \), we have

\[
\hat{w}^\pi(sr, tr) = \pi(sr)w^\pi(sr, tr) = \pi(sr) \int_G w(sr p, tr p) \pi(p) dp = \pi(s) \int_G w(srp, trp) \pi(p) dp = \pi(s) \int_G w(sp, tp) \pi(p) dp = \hat{w}^\pi(s,t),
\]

10
implying $\tilde{w}_{k,j}^n \in V_{iv}^\infty(G)$. By Theorem 3.1,
\begin{equation}
\tilde{w}_{k,j}^n = Nu
\end{equation}
for some $u \in M_{cb}A(G)$. Moreover, if $w$ vanishes on $E^*$ then $u$ vanishes on $E$.
We claim that $Nu \cdot T = 0$ for any operator $T$ and $u \in M_{cb}A(G)$ such that supp$(T) \subset E^*$, null $u \supset E$. In fact, since $E$ is a set of local spectral synthesis, given $w \in A(G)$ with compact support, $uw$ can be approximated by $u_\alpha \in P_{0}(E)$ and therefore $N(uw)$ is a $V^\infty(G)$-limit of $N_{u_\alpha}$, vanishing on pseudo-neighborhoods of $E^*$. By [ShT1, Theorem 4.3],
\[ \langle T, \Psi \rangle = 0 \] for any $\Psi \in \Phi_0(E^*)$. Therefore $\langle Nu_\alpha \cdot T, F \rangle = \langle T, (Nu_\alpha)F \rangle = 0$ for any $F \in T(G)$ implying $Nu_\alpha \cdot T = 0$ and $N(uw) \cdot T = 0$. As $\langle Nu \cdot T, (Nw)F \rangle = 0$ for any $w \in A(G)$ with compact support and $F \in T(G)$ it is enough to see now that the subspace, $\mathcal{M}$, generated by $(Nw)F$, where $F \in T(G)$ and $w \in A(G)$ with compact support, is dense in $T(G)$. As null $\mathcal{M} = \emptyset$, this is true by an analogue of Wiener's Tauberian Theorem [ShT1, Corollary 4.3].
We obtain by (4.10) that for any $w \in V^\infty(G)$ which is compactly supported and vanishes on $E^*$
\[ \tilde{w}_{k,j}^n \cdot T = 0. \]
Therefore by (4.9)
\[ w_{k,j}^n \cdot T = \left( \sum_i v_{ij}^n(s) \tilde{w}_{k,j}^n(s, t) \right) \cdot T = 0, \]
Let $K$ be a compact set such that supp$(w) \subset K \times K$ and supp$(T) \subset K \times K$. Then since $T = M_{xK}TM_{xK}$, for compactly supported $h \in L^1(G)$ we have
\[ \langle T, h \cdot w \rangle = \langle M_{xK}TM_{xK}, h \cdot w \rangle = \langle T, \chi_K(t)\chi_K(s) \int_G w(s, r) h(r) dr \rangle = \langle T, \int_G w(s, r) \chi_{K^{-1}}(r) h(r) dr \rangle = \langle T, h \chi_{K^{-1}} \cdot w \rangle. \]
Take $f \in L^\infty(G)$, $g \in L^\infty(G)$, supp$(f) \subset K$, supp$(g) \subset K$, and set $\omega = f \otimes g$. Then
\[ \langle \omega \cdot T, u_{k,j}^n \chi_{K^{-1}} \cdot w \rangle = \langle T, (u_{k,j}^n \chi_{K^{-1}} \cdot w) \rangle = \langle T, u_{k,j}^n \omega \rangle = \langle u_{k,j}^n \cdot T, w \rangle = 0. \]
Hence for finite linear combinations $\sum_i c_i u_i$ of matrix coefficients
\[ \langle \omega \cdot T, \sum_i c_i u_i \chi_{K^{-1}} \cdot w \rangle = 0. \]
Take now an approximate identity $\{e_\alpha\}$ consisting of non-negative continuous functions with compact support in $L^1(G)$. We can assume that $K^{-1}K$ contains the supports of $e_\alpha$'s.
Then, by [Di, 13.6.5], $\Delta^{1/2} e_\alpha$ can be approximated in $L^1(G)$ by finite linear combinations $\sum_{i=1}^d c_i u_i \chi_{K^{-1}}K$. This yields
\[ 0 = \langle \omega \cdot T, (\Delta^{1/2} e_\alpha) \cdot w \rangle = \langle \omega \cdot T, (e_\alpha \otimes w) \rangle \]
and therefore $0 = \langle \omega \cdot T, w \rangle = \langle w \cdot T, \omega \rangle$. Finally, we obtain $w \cdot T = 0$. 
\[ \square \]
Corollary 4.11. Let $G$ be a s.c.l.c. group.
a) Then a compact set $E \subset G$ is a set of spectral synthesis for $A(G)$ if and only if $E^*$ is
a set of operator synthesis with respect to Haar measure.
b) Assume that $A(G)$ has an approximate identity. Then a closed set $E \subset G$ is a set of
spectral synthesis for $A(G)$ if and only if $E^*$ is a set of operator synthesis with respect to
Haar measure.

Proof. Follows from Corollary 4.4, Corollary 4.5 and Theorem 4.10. □

5. Ditkin sets and operator Ditkin sets.

Our goal in this section is to find a connection between Ditkin sets and operator Ditkin
sets. Let $G$ be a locally compact group and let $m$ be the Haar measure on $G$. A closed
subset $E \subset G$ is said to be a (local) Ditkin set if for any $f \in I_A(E)$ ($f \in I^+_A(E)$) there
exists a sequence $\{\tau_n\}_{n=1}^{\infty}$ such that $\tau_n \in J^+_A(E)$ ($n = 1, 2, \ldots$) and $\tau_nf \rightarrow f$ as $n \rightarrow \infty$.
It is called a strongly Ditkin set if such a sequence $\{\tau_n\}$ can be chosen uniformly for all
functions $f \in I_A(E)$.

In a similar way operator Ditkin sets were defined in [ShT1]. By [ST] the elements of
$V^\infty(G)$ are the multipliers of $T(G)$, i.e. $\omega \omega \subset \omega$ if $\omega \in V^\infty(G)$ and $\omega \in T(G)$. We call a pseudo-closed subset $E \subset G \times G$ an $m$-Ditkin set if for any $w \in \Phi(E)$ there exists a sequence $\tau_n \in V^\infty(G)$ such that $\tau_n$ vanishes on a pseudo-neighbourhood of $E$ ($n = 1, 2, \ldots$) and

$$||\tau_n w - w||_{T(G)} \rightarrow 0, \text{ as } n \rightarrow \infty.$$  

$E \subset G \times G$ is said to be a strong $m$-Ditkin set if such a sequence $\{\tau_n\}_{n=1}^{\infty}$ can be chosen uniformly for all $w \in T(G)$.

If $G$ is a compact metrisable abelian group, it is known that $E = \{0\}$ is a strong Ditkin
set. Moreover, this set satisfies the following three conditions: (1) $E$ is a set of synthesis;
(2) there exist open sets $\Omega_n$ containing $E$ such that

$$\Omega_{n+1} \subset \Omega_n \quad n = 1, 2, \ldots \text{ and } \cap_{n=1}^{\infty} \tilde{\Omega}_n = E;$$

(3) there exists a sequence $\{u_n\}$ with $1 - u_n \in J^+ (E)$, $n = 1, 2, \ldots$, satisfying the following two conditions:

$$u_n(x) = 0 \text{ for all } x \notin \Omega_n,$$

$$||u_n|| \leq 1 + \varepsilon_n,$$

where $\{\varepsilon_n\}$ is a sequence decreasing to zero.

Note that any closed subset $E$ of the spectrum of a semisimple, regular, commutative
Banach algebra $A$ satisfying the conditions (1), (2) and (3) is a strong Ditkin set for $A$ ([D]).

Let $Z$ be a standard Borel space and let $f : G \rightarrow Z$ and $g : G \rightarrow Z$ be Borel functions. Consider

$$E = \{(s, t) : f(s) = g(t)\} \subset G \times G.$$  

If $G$, $Z$ are compact metrisable spaces, $f, g$ are continuous functions and $A = V(G) = C(G) \hat{\otimes} C(G)$, the Varopoulos algebra, then $E$ is shown in [D] to satisfy the conditions (1),
(2) and (3) and therefore to be a strong Ditkin set for $V(G)$. Knowing that $E$ is a set
of synthesis with respect to \( m \) ([ShT1, Theorem 4.8]) we can use a similar argument to show the following statement.

**Proposition 5.1.** \( E = \{ (s, t) : f(s) = g(t) \} \subset G \times G \) is a strong \( m \)-Ditkin set.

**Proof.** First we embed \( Z \) into the torus, \( \mathbb{T}_\infty \), of infinite dimension: by [T, Theorem A.1] there exists a Borel injective mapping \( \psi : Z \to \mathbb{T}_\infty \). Consider a mapping \( \rho : G \times G \to \mathbb{T}_\infty \) given by

\[
\rho(s, t) = \psi(f(t)) - \psi(g(s)),
\]

where the subtraction is taken with respect to the group structure on \( \mathbb{T}_\infty \). Then \( \rho^{-1}(\mathbb{T}_\infty) = E \).

As \( \{ 0_{\mathbb{T}_\infty} \} \) satisfies (1), (2), (3) in \( A(\mathbb{T}_\infty) \), there exist open sets \( \Sigma_n \subset \mathbb{T}_\infty \) such that \( 0_{\mathbb{T}_\infty} \in \Sigma_n \), \( \Sigma_n \subset \Sigma_{n+1} \), \( n = 1, 2, \ldots \), \( \bigcap \Sigma_n = \{ 0 \} \) and a sequence of functions \( w_n \in A(\mathbb{T}_\infty) \) such that \( 1 - w_n \in J^*_A(0_{\mathbb{T}_\infty}) \), \( w_n(x) = 0 \) for \( x \notin \Sigma_n \) and \( \| w_n \|_A \leq 1 + \varepsilon_n \) (\( \varepsilon_n \to 0 \), \( \varepsilon_n > 0 \)).

Define \( \Omega_n = \rho^{-1}(\Sigma_n) \). As \( \psi \circ f \) and \( \psi \circ g \) are Borel mappings for given \( m > 0 \) there exist by Lusin’s theorem closed subsets \( A_m \subset G \) and \( B_m \subset G \) such that \( \rho \) is continuous on \( A_m \times B_m \) and \( |G \setminus A_m| < 1/m, |G \setminus B_m| < 1/m \). We can choose those subsets increasing in \( m \). Therefore

\[
\Omega_n \cap (A_m \times B_m) = \{ (x, y) \in A_m \times B_m : \rho(x, y) \in \Sigma_n \}
\]
is open in \( A_m \times B_m \) for all \( n \) and

\[
E \cap (A_m \times B_m) = \bigcap_{n=1}^{\infty} \rho^{-1}(\Sigma_n) \cap (A_m \times B_m) 
\subseteq \bigcap_{n=1}^{\infty} \Omega_n \cap (A_m \times B_m) 
\subseteq \bigcap_{n=1}^{\infty} \rho^{-1}(\Sigma_n) \cap (A_m \times B_m) = E \cap (A_m \times B_m)
\]

Set \( u_n = w_n \circ \rho \). First we show that \( u_n \in V^\infty(G) \). In fact, if \( w_n = \sum_{\chi \in \hat{T}_\infty} a_{\chi, n} \chi \) with \( \sum_{\chi \in \hat{T}_\infty} |a_{\chi, n}| = \| w_n \|_A \), then

\[
w_n(\rho(s, t)) = \sum_{\chi \in \hat{T}_\infty} a_{\chi, n} \chi(\psi(f(s)))\overline{\chi(\psi(g(t)))}
\]

and our claim follows since

\[
\sum_{\chi \in \hat{T}_\infty} |a_{\chi, n}|^2 \| \chi(\psi(f(s))) \|^2 = \sum_{\chi \in \hat{T}_\infty} |a_{\chi, n}|^2 \| \chi(\psi(g(t))) \|^2 = \sum_{\chi \in \hat{T}_\infty} |a_{\chi, n}| = \| w_n \|_A.
\]

Moreover, by Theorem 3.1, \( \| u_n \|_{V^\infty} \leq \| w_n \|_A \leq 1 + \varepsilon_n \), \( u_n = 0 \) on \( \Omega_n^c \) and \( \tau_n = 1 - u_n \) vanishes on a pseudo-neighbourhood of \( E \).

We next show that for given \( w \in \Phi(E) \), \( \| \tau_n w - w \| \to 0 \), as \( n \to 0 \). Assume first that \( \text{supp} (w) \subset K \times K \), where \( K \) is a compact set. Then \( w = w_1 + w_2 + w_3 + w_4 \), where \( w_1 = w_{X_{A_m \times B_m}}, w_2 = w_{X(G \setminus A_m) \times B_m}, w_3 = w_{X_{A_m \times (G \setminus B_m)}}, w_4 = w_{X_{(G \setminus A_m) \times (G \setminus B_m)}} \). For given \( \varepsilon > 0 \) there exists \( M > 0 \) such that \( \| w_i \|_{T(G)} < \varepsilon \) for each \( m \geq M \) and \( i = 2, 3, 4 \).

Indeed, since the sequence \( \{ A_m \} \) is increasing in measure to \( G \), by Lebesgue’s theorem

\[
\int_{G \setminus A_m} \sum_{i=1}^{\infty} |f_i(r)|^2 dr \to 0 \quad \text{as} \quad m \to \infty
\]

and for \( w_i^2 \) we have

\[
\| w_i^2 \|_{T(G)}^2 \leq \int_{G \setminus A_m} \sum_{i=1}^{\infty} |f_i(r)|^2 dr \int_{G \setminus A_m} \sum_{i=1}^{\infty} |g_i(r)|^2 dr \to 0.
\]
Similarly, \(||w_i^{m_i}||_{\gamma_i}^{(G)} \to 0\), \(i = 3,4\). Fix now \(m > M\). By [ShT1, Theorem 4.8] \(E\) is a set of operator synthesis with respect to Haar measure and by [ShT1, Lemma 6.1] so is \(E \cap (A_m \times B_m)\). As \(E \cap (A_m \times B_m)\) is closed, by [A, 2.29] there exists \(\psi \in T(G)\), supp \(\psi \subset A_m \times B_m\), vanishes on an open neighborhood \(\Omega \subset A_m \times B_m\) of \(E \cap (A_m \times B_m)\) and \(||w_i^{m_i} - \psi|| < \varepsilon\). By (5.12),
\[
\cap_{n=1}^{\infty} \Omega_n \cap (A_m \times B_m) \cap K \times K \subset \Omega \cap K \times K
\]
and so \(\Omega_n \cap (A_m \times B_m) \cap K \times K \subset \Omega \cap K \times K\) for \(n > N\), \(N\) is large enough. Thus \(u_n \psi \chi_{K \times K} = 0\) for \(n > N\). We get
\[
||\tau_n w_i^{m_i} - w_i^{m_i}|| = ||\tau_n (w_i^{m_i} - \psi) \chi_{K \times K} - u_n \psi \chi_{K \times K} - (w_i^{m_i} - \psi) \chi_{K \times K}|| \leq (1 + ||\tau_n||_V) \varepsilon
\]
and
\[
||\tau_n w - w|| \leq ||\tau_n w_i^{m_i} - w_i^{m_i}|| + \sum_{i=2}^{4} ||(\tau_n - 1) w_i^{m_i}|| \leq 4(1 + ||\tau_n||_V) \varepsilon.
\]
As \(G\) is \(\sigma\)-compact there exist compact subsets \(K_i\) such that \(K_i \subset K_{i+1}\) and \(\cup_{i=1}^{\infty} K_i = G\), and therefore for any \(w \in T(G)\), \(w = \lim w \chi_{K_i \times K_i}\) in \(T(G)\) giving that \(||\tau_n w - w|| \to 0\) for any \(w \in \Phi(E)\).

**Corollary 5.2.** Any finite union of sets of type (5.11) is a Dikin set.

**Proof.** It follows from Proposition 5.1 and [ShT1, Theorem 7.1].

**Remark 5.3.** It follows, in particular, from Corollary 5.2 that finite unions of sets of type (5.11) are sets of operator synthesis. This was also proved by Todorov in [To] using another method.

We will now establish a connection between (strong) Dikin sets for \(A(G)\) and (strong) operator Dikin sets.

For \(w \in T(G)\), define as in [V]
\[
Qw(s) = \int_G w(sr, r) dr.
\]
If \(w = \sum_{i=1}^{\infty} f_i \otimes g_i\) with \(\sum_{i=1}^{\infty} ||f_i||_2^2 \cdot \sum_{i=1}^{\infty} ||g_i||_2^2 < \infty\). Then
\[
Qw(s) = \sum_{i=1}^{\infty} (g_i * f_i)(s^{-1}) \in A(G)
\]
and, moreover, \(||Qw|| \leq ||w||_{T(G)}\). Thus \(Q : T(G) \to A(G)\) defines a contraction operator.

**Theorem 5.4.** Let \(G\) be a second countable locally compact group. If \(E^*\) is a strong \(m\)-Dikin set then \(E\) is a local Dikin set. If \(E\) is a strong Dikin set then \(E^*\) is an \(m\)-Dikin set.

**Proof.** Assume first that \(E^*\) is a strong \(m\)-Dikin set. Let \(\{\Psi_n\}_{n=1}^{\infty} \subset V^\infty(G)\) be a sequence from the definition of a strong \(m\)-Dikin set and let \(u \in I_\epsilon(E)\). For a compact subset \(K \subset G\) containing the support of \(u\), define \((Nu)_K(s,t) = u(st^{-1}) \chi_K(t)\). We have \((Nu)_K(s,t) = \chi_{MK}(s)u(st^{-1}) \chi_K(t)\), where \(M = \text{supp}(u)\). As \(u(st^{-1}) \in V^\infty(G)\) and \(|MK| < \infty, |K| <\)
$\infty$, it yields $(Nu)_K \in T(G)$. Moreover, $(Nu)_K$ vanishes on $E^\circ$. Therefore, $\|\Psi_n(Nu)_K - (Nu)_K\|_{T(G)} \to 0$ as $n \to \infty$. Thus given $\varepsilon > 0$, there exists $N$ such that for $n > N$

$$
\|Q(\Psi_n(Nu)_K) - Q((Nu)_K)\|_A \leq \|\Psi_n(Nu)_K - (Nu)_K\|_{T(G)} < \frac{\varepsilon}{|K|}
$$

On the other hand,

$$
Q(\Psi_n(Nu)_K)(s) = \int_G \Psi_n(sr, r)Nu(sr, r)\chi_K(r)dr = \int_G \Psi_n(sr, r)u(s)\chi_K(r)dr
$$

= $u(s)\int_G \chi_{MK}(sr)\Psi_n(sr, r)\chi_K(r)dr = u(s)Q(\Psi_n(\chi_{MK} \otimes \chi_K))(s)$

and similarly $Q((Nu)_K) = u[K]$ giving us

$$
\|Q(\Psi_n(Nu)_K) - Q((Nu)_K)\|_A = \|uw_n - u[K]\|,
$$

where $w_n = Q(\Psi_n(\chi_M \otimes \chi_K))$. We obtain now that for $\tau_n = w_n/[K]$,

$$
\|u\tau_n - u\|_A < \frac{|K|\varepsilon}{|K|} = \varepsilon.
$$

Hence $E$ is a local Ditkin set.

Suppose $E$ is a strong Ditkin set. Let $v_n \in J_A^0(G)$ be a sequence such that $\|v_n f - f\|_A \to 0$ as $n \to \infty$ for any $f \in I(E)$. By Proposition 3.1, $Nv_n \in V^\infty(G)$, $n = 1, 2, \ldots$, and

$$
(5.13) \quad \|\langle (Nu)_n \rangle - Nf\|_{V^\infty} \leq \|v_n f - f\|_A \to 0.
$$

Next we show that $(Nu)_n w \cdot T \to w \cdot T$ ultra-weakly for any compactly supported $T$ in $B(L^2(G))$ and any compactly supported $w$ in $V^\infty(G)$ such that $w = 0$ on $E^\circ$ using arguments similar to the ones in the proof of Theorem 4.10.

Assume $\text{supp}(w) \subseteq K \times K$, for a compact set $K \subseteq G$. Let $w_{k_j}^n$ and $\hat{w}_{k_j}^n$ be $V^\infty$-functions as defined in (4.5) and let $u_{k_j}^n$ be the matrix coefficient $(\pi(\cdot) e_{k_j}, \pi(n))$, $\pi \in \hat{G}$. We have $w_{k_j}^n(s,t) = \sum_{l \in L} u_{k_j l}^n(s)\tilde{w}_{k_j}^n(t, u_{k_j l}^n N(u) \Psi)$ by (4.7). Hence, for $u \in A(G)$, $\Psi \in T(G)$,

$$
\|\langle (Nu)_n - 1 \rangle_{w_{k_j}^n \cdot T, N(u) \Psi}\| \leq \sum_{l \in L} \|\langle (Nu)_n - 1 \rangle_{\tilde{w}_{k_j}^n \cdot T, u_{k_j l}^n N(u) \Psi}\|
$$

= $\sum_{l \in L} \|\langle (Nu)_n - 1 \rangle_{\tilde{w}_{k_j}^n \cdot T, N(u) \Psi}\| + \sum_{l \notin L} \|\langle (Nu)_n - 1 \rangle_{\tilde{w}_{k_j}^n \cdot T, u_{k_j l}^n N(u) \Psi}\|$

where $L$ is a finite set. For the infinite sum we can apply the estimate (4.9) with $(Nu)_n - 1)$ instead of $\Psi$, so that for given $\varepsilon > 0$ there exists a finite subset $L$ such that

$$
\sum_{l \notin L} \|\langle (Nu)_n - 1 \rangle_{\tilde{w}_{k_j}^n \cdot T, u_{k_j l}^n N(u) \Psi}\| = \sum_{l \notin L} \|\langle \tilde{w}_{k_j}^n \cdot T, u_{k_j l}^n N(u) \Psi\| < \varepsilon
$$

For the finite sum we note first that $\tilde{w}_{k_j}^n = N(v_{k_j}^n)$ for some $v_{k_j}^n \in M_{\Phi}(A(G)$ by (4.10). Then by (5.13) there exists $M > 0$ such that for any $n > M$,

$$
\sum_{l \in L} \|\langle (Nu)_n - 1 \rangle_{\tilde{w}_{k_j}^n \cdot T, u_{k_j l}^n N(u) \Psi}\| = \sum_{l \in L} \|T, u_{k_j l}^n (Nu)_n - 1)N(v_{k_j}^n u) \Psi\|
$$

= $\sum_{l \in L} \|T\| \cdot \|\langle (Nu)_n - 1 \rangle_{N(v_{k_j}^n u) \Psi}\|_{V^\infty} \|\Psi\|_{T(G)} < \varepsilon
$$
We obtain,

\[
((Nv_n - 1)w^\pi_{kj} \cdot T, N(u)\Psi) \to 0, \ n \to \infty.
\]

As in the proof of Theorem 4.10, it yields

(5.14) \quad \langle (Nv_n - 1)w^\pi_{kj} \cdot T, \Psi \rangle \to 0, \ n \to \infty

for any $\Psi \in T(G)$, since $\{Nv_n\}$ is bounded in norm. Using the same arguments as in the end of the proof of Theorem 4.3 we have that for big enough compact set $K$ there exists a linear combination $u = \sum_{i=1}^d c_iu_i$ of matrix coefficients such that

\[
||w - u_{\chi K^{-1}K} \cdot w||_{T(G)} < \varepsilon.
\]

Thus for $\omega \in T(G)$, supp($\omega$) $\subset K \times K$,

\[
\left| \langle (Nv_n - 1)w \cdot T, \omega \rangle \right| \leq \left| \langle (Nv_n - 1) \cdot T, \omega(w - u_{\chi K^{-1}K} \cdot w) \rangle \right| + \left| \langle (Nv_n - 1) \cdot T, \omega(u_{\chi K^{-1}K} \cdot w) \rangle \right|.
\]

The first summand is less than $C\varepsilon$ for some constant $C$, for $n$ large enough, as $\{Nv_n\}$ is bounded in norm. As $\omega(w^\pi_{kj} \cdot w) = \omega w^\pi_{kj}$ by (4.5) for all $k, j, \pi$, we have by (5.14)

\[
\langle (Nv_n - 1) \cdot T, \omega(u_{\chi K^{-1}K}^\pi \cdot w) \rangle = \langle (Nv_n - 1)w^\pi_{kj} \cdot T, \omega \rangle \to 0, n \to \infty,
\]

and hence $\left| \langle (Nv_n - 1) \cdot T, \omega(u_{\chi K^{-1}K} \cdot w) \rangle \right| < \varepsilon$ for $n$ large enough. Thus,

\[
\langle (Nv_n - 1)w \cdot T, \omega \rangle \to 0
\]

for each $\omega \in T(G)$. Hence $(Nv_n)\omega \omega \to u\omega$ weakly for each $\omega \in T(G)$. As the set of all linear combinations of $u\omega$, where $w \in V^\infty$ and $w = 0$ on $E^\ast$ and $\omega \in T(G)$, is dense in $\Phi(E)$ ([ShT2, Proposition 5.3]), $(Nv_n)\omega \to \omega$ weakly for any $\omega \in \Phi(E)$. Taking if necessary convex linear combinations of the $Nv_n$’s, we obtain elements $w_n \in V^\infty(G), n \in \mathbb{N}$, such that $||w_n\omega - \omega||_{T(G)} \to 0$ as $n$ tends to infinity. Clearly, the sequence $\{w_n\}_n$ satisfies the necessary conditions. \hfill Q.E.D.

**Corollary 5.5.** Any closed subgroup $H$ of $G$ is a local Ditkin set.

**Proof.** We have $H^\ast = \{(s, t) : f(s) = f(t)\}$, where $f : G \to G \setminus H$, $t \mapsto tH$. As $G$ is metrizable, by [HRI, (8.14)], $G \setminus H$ is metrizable. The statement now follows from Proposition 5.1 and Theorem 5.4. \hfill Q.E.D.

For $G$ amenable the statement was obtained in [FKLS] showing that $I_A(H)$ has a bounded approximate identity. For arbitrary locally compact $G$ and $H$ a closed neutral subgroup it was proved in [DD]. Note that there are closed subgroups of l.c.s.c. groups which are not neutral (see [RD, p.107]).
