COMPUTER EXERCISE 6  
IMAGE FILTERING AND FEATURE EXTRACTION  
SPATIAL STATISTICS AND IMAGE ANALYSIS, TMS016

---

## 1 Introduction

The purpose of this computer exercise is to give an introduction to image filtering and feature extraction. When in doubt about how to use a specific function in Matlab, use `help` and `doc` to get more information.

## 2 Image filtering

Throughout the exercise, we will use the image `rice.png` which is supplied with Matlab. Load it by writing `I = imread('rice.png');` and convert it to double values.

- Test filtering the image with some different smoothing filters, using the function `conv2`.
- Filter the image using horizontal and vertical edge detection filters and compute the Prewitt-filtered image.

## 3 Morphological operations

- Create a binary image by segmenting the image into two classes based on the grayscale values using a GMM (as in Computer Exercise 5).
- Compute the image erosion, dilation, and opening using a circular structure element with different radii  $r$  and plot the results. A circular structure element can be constructed using `strel('disk',r)`, and you can compute the erosion, dilation, and opening using `imerode`, `imdilate`, and `imopen`, respectively. Make sure that you understand what these operations are doing.

## 4 Improved segmentation

A problem with segmenting the image using a mixture model is that the intensity of the background has a clear spatial trend. We can therefore improve the segmentation by first estimating the background, removing it, and then segmenting the updated image.

- Use `imopen` with a circular structure element to estimate the background of the grayscale image. Plot the image opening for different values of  $r$  to find a suitable value.
- Subtract the estimated background from the image and plot the results.
- Segment the image into two classes using a GMM and compare the result to the segmentation without the background removal.
