

PDE Project Course

3. *C++ programming*

Karin Kraft and Johan Jansson

Department of Mathematical Sciences

Lecture plan

- History and overview
- Variables and basic operators
- The conditional statement: `if`
- Iteration: `for` and `while`
- Functions
- Classes
- Inheritance
- ...

History and overview

C++

- Invented by Bjarne Stroustrup at AT&T Bell Laboratories in the early 1980's.
- Extends the C programming language to provide support for object-oriented programming.
- Widely used.
- Standardized by ANSI.

Hello world in C++

```
#include <iostream>

using namespace std;

int main()
{
    cout << ``Hello world!`` << endl;
    return 0;
}
```

Hello world in C++

```
#include <iostream>

using namespace std;

int main()
{
    int n = 10;
    for (int i = 0; i < n; i++)
        cout << ``Hello world!`` << endl;
    return 0;
}
```

A basic C++ vocabulary

- Fundamental data types:

`int, float/double, bool, (char)`

- Conditions and loops:

`if, else`

`for, while`

- Classes:

`class, public, private`

- General:

`#include`

Comments

Use `//` and not `/*` . . . `*/` for comments:

```
// This is a comment
```

Variables and basic operators

Definition of a variable

- Note how in the Hello World-program each variable is defined as

```
VariableType nameOfVariable;
```

- A variable must be introduced before it is used.
- A variable can be defined almost anywhere in the code.

Fundamental data types

Type	Represents
<code>int</code>	Integers: <code>...</code> , <code>-2</code> , <code>-1</code> , <code>0</code> , <code>1</code> , <code>2</code> , <code>...</code>
<code>float</code>	Real numbers: <code>0.1</code> , <code>1.34e-15</code> , <code>-4.2e-6</code> , <code>...</code>
<code>bool</code>	Boolean value: <code>true</code> or <code>false</code>
<code>char</code>	Characters / bytes: <code>'a'</code> , <code>'F'</code> , <code>'/'</code> , <code>...</code>

`int` exists also in the versions `short` and `long`
`float` exists also in the version `double`

Examples

```
int n = 10;  
int a = 1;  
float x = 1.24;  
double y = 3.14159265358979;  
a = a + n;  
y = 2.0 * y;  
x = (1.25 / x) * 24.2;  
int b;  
int age = 20;  
char c = 'a';  
b = 17 / 2;  
bool p = true;
```

Arithmetic operators

Operator	Represents
+	Addition
-	Subtraction
*	Multiplication
/	Division

- Note that there is no \wedge operator representing powers x^y !
- Shortcuts: +=, -=, *=, /=, ++, --

Examples

```
int a = 2;  
a += 3;  
a *= 7;  
a++;      //instead of a = a + 1;  
a /= 5;   //instead of a = a / 5;  
a--;  
a++;  
a += 7;   //instead of a = a + 7;
```

The conditional statement:

`if`

The `if`-statement

The basic conditional statement in C++ is:

```
if ( <condition> )  
{  
    ...  
}  
else  
{  
    ...  
}
```

Examples

```
if ( a > b || a < b )
    cout << ``a is not equal to b`` << endl;

if ( a > 3 && b > 3 )
    cout << ``a and b are greater than 3`` << endl;
elseif ( a > 3 )
    cout << ``a is greater than 3`` << endl;
elseif ( b > 3 )
    cout << ``b is greater than 3`` << endl;
else
    cout << ``neither a nor b greater than 3`` << endl;
```

Note also: ==, !=, >= and <=

Iteration: `for` and `while`

The `for`-statement

The basic iterative statement in C++ is:

```
for (<initialisation>; <condition>; <update>)  
{  
  
    ...  
  
}
```

Examples

```
for (int i = 0; i < 10; i++)  
    cout << ``i = `` << i << endl;
```

```
for (int j = 10; j > 0; j--)  
    cout << ``j = `` << j << endl;
```

The `while`-statement

A somewhat different iterative statement in C++ is:

```
while (<condition>)  
{  
  
    ...  
  
}
```

Examples

```
int i = 0;
while ( i < 10 )
{
    ...
    i++;
}
```

```
while ( true )
{
    ...
}
```

Functions

Declaration of a function

A function is a part of a program that can be called from other parts of the program.

```
<return type> <function name>(<variable>, ...)  
{  
  
    ...  
  
}
```

Example

```
int max(int a, int b)
{
    if ( a > b )
        return a;
    else
        return b;
}

int main()
{
    int a = 3;
    int b = 5;
    int c = max(a, b);
    return 0;
}
```

Classes

Declaration of a class

```
class Vector {
public:
    Vector(int n);           // Constructor
    ~Vector();              // Destructor

    void resize(int n);     // A function
    void size( int & n );   // Another function
private:
    int n_;                 // Size of the vector
    double_* values;       // The values
};
```

Private/Public

- Members of a class can be either *private* or *public*
- The members are by default supposed to be *private*
- *Public* members have to be declared *public* explicitly
- *Public* members can be used and reached from outside the class
- *Private* members can only be used by other members of the class class

Member data

The values stored in a class object is called *member data*.

Member data is usually declared *private*:

```
private:  
    int n_i  
    double* values_i
```

Member functions

Functions that belong to a class object are called *member functions*.

A class usually has a set of *public* member functions:

```
public:  
    void resize(int n);  
    int  size();
```

Constructors

The constructor function is called when an object of the class is created:

```
Vector x(10);
```

Now we have an object of the class *Vector* called *x*. We can call a member function with

```
x.resize( 20 )
```

Destructor

The destructor function is called when the object is destroyed, which happens when the object goes *out of scope*. This happens when we reach the end of the { } block in which the object is defined.

User-defined operators

To use `Vector` objects as vectors, we implement the index operator `()`, the assignment operator `=`, and the arithmetic operators `+`, `-`, `*` and `/`.

```
class Vector {
public:
    ...
    double& operator()(int index);
    const Vector operator+(const Vector& vector);
    const Vector operator-(const Vector& vector);
    const Vector operator*(double a);
    const Vector operator/(double a);
    ...
};
```

Using the Vector class

```
Vector x(10);
```

```
Vector y(10);
```

```
for (int i = 0; i < 10; i++)
```

```
    x(i) = (double) i*i;
```

```
y = x + y;
```

```
x = x / 5.0 + y + x;
```

Inheritance

Parent class

```
class Figure {
public:
    Figure();           // Constructor
    ~Figure();         // Destructor

    virtual float area() = 0; // A function
    virtual float circumreference() = 0; // A function
};
```

Derived Class Rectangle

```
class Rectangle : public Figure() {
public:
    Rectangle( double b, double h ):Figure(),
        base_( b ), height_( h ){ }
    ~Rectangle(){}
    float area(){
        return base_ * height_;
    }
    float circumreference(){
        return 2 * base_ + 2 * height_;
    }
private:
    double base_;
    double height_;
};
```

Derived Class Circle

```
class Circle : public Figure() {
public:
    Circle( double r ) : Figure(),
        radius_( r ) {}
    ~Circle(){}
    float area(){
        return 3.14 * radius_ * radius_;
    }
    float circumreference(){
        return 3.14 * 2 * radius_;
    }
private:
    double radius_;
};
```

References

References

A reference is an alias, i.e. an alternate name for some variable.

```
int a = 5;  
int& b = a;
```

```
b += 7; // Now a and b equal 12!
```

References as function arguments

To allow a function to change a value, we can make the argument a reference:

```
void max(int a, int b, int& max_val)
{
    if ( a > b )
        max_val = a;
    else
        max_val = b;
}
```

References as function arguments

Another reason to use references can be to avoid unnecessary copying of function arguments:

```
void max(Vector& x, double & maximum)
{
    maximum = x(0);
    for (int i = 1; i < x.size(); i++)
        if ( x(i) > maximum )
            maximum = x(i);
}
```

Continuation

```
void main() {  
    Vector reallyHugeVector( 1000000 );  
    double maximum;  
    ...  
    max( reallyHugeVector, maximum );  
}
```

Structuring your program

Declaration and definition

A function does not have to be defined at the same time as it is declared:

```
int max(int a, int b); // Somewhere...
```

```
int ClassName::max(int a, int b) // and somewhere else
{
    if ( a > b )
        return a;
    else
        return b;
}
```

Header files and `cpp`-files

- Put all your declarations of a class in one file called the header file.
- Name the file `ClassName.h`
- Put the implementation of a class in a `cpp`-file.
- Name the file `ClassName.cpp`
- Use one file to one class.
- Include the corresponding header file.

Comment your code

- Write comments in your code
- Write short but good comments
- Your memory is not as good as you think!

Compiling a C++ program

Compiling Hello World I

```
elrond> g++ helloworld.cpp
elrond> ls
a.out  helloworld.cpp
elrond> ./a.out
Hello world!
```

Compiling Hello World II

```
elrond> g++ -o helloworld helloworld.cpp
elrond> ls
a.out  helloworld  helloworld.cpp
elrond> ./helloworld
Hello world!
```

Compiling Hello World III

```
elrond> g++ -c helloworld.cpp
elrond> ls
a.out  helloworld  helloworld.cpp  helloworld.o
elrond> g++ -o helloworld helloworld.o
elrond> ./helloworld
Hello world!
```

Writing a Makefile

```
CXX      = g++
CFLAGS   = -O2
LFLAGS   =
DEST     = helloworld
OBJECTS  = helloworld.o
CXXLINK  = $(CXX) -o $@

all: $(DEST)
clean:
    -rm -f *.o core *.core $(OBJECTS) $(DEST)
$(DEST): $(OBJECTS)
    $(CXXLINK) $(OBJECTS) $(CFLAGS) $(LFLAGS)
```

Compiling Hello World IV

```
elrond> make
g++ -c -o helloworld.o helloworld.cpp
g++ -o helloworld helloworld.o -O2
elrond> ./helloworld
Hello world!
elrond> make clean
rm -f *.o core *.core helloworld.o helloworld
```

Introduction to DOLFIN

Introduction to DOLFIN

- An adaptive finite element solver for PDEs and ODEs
- Developed at the Department of Computational Mathematics
- Written in C++
- Only a solver. No mesh generation. No visualization.
- Licensed under the GNU GPL
- <http://www.phy.chalmers.se/dolfin>

GNU and the GPL

- Makes the software free for all users
- Free to modify, change, copy, redistribute
- Derived work must also use the GPL license
- Enables sharing of code
- Simplifies distribution of the program
- Linux is distributed under the GPL license
- See <http://www.gnu.org>

Three levels

- Simple C/C++ interface for the *user* who just wants to solve an equation with specified geometry and boundary conditions.
- New algorithms are added at *module level* by the developer or advanced user.
- Core features are added at *kernel level*.

C++ examples in DOLFIN

- We will start looking at some of the basic infrastructure DOLFIN provides: linear algebra, input/output, mesh representation
- Demonstration

Examples
