Uses and misuses of mathematics in analysing social networks

Peter Hegarty

Department of Mathematics, CTH/GU

11 June, 2014

Part 1: The sociological notion of “balance”

Zachary’s graph by the numbers

The explanation

The correct interpretation of the triad counts in Zachary’s graph

Part 2: Preferential attachment models and power laws

The precise model of Bollobás et al

Their theorem

The good, the bad and the ugly

Part 3: Opinion dynamics

► First part:

Part 1: The sociological notion of “balance”

Zachary’s graph by the numbers

The explanation

The correct interpretation of the triad counts in Zachary’s graph

Part 2: Preferential attachment models and power laws

The precise model of Bollobás et al

Their theorem

The good, the bad and the ugly

Part 3: Opinion dynamics

► First part:

The friend of my friend is my friend

Part 1: The sociological notion of “balance”

Zachary’s graph by the numbers

The explanation

The correct interpretation of the triad counts in Zachary’s graph

Part 2: Preferential attachment models and power laws

The precise model of Bollobás et al

Their theorem

The good, the bad and the ugly

Part 3: Opinion dynamics

▶ First part:

The friend of my friend is my friend

▶ Second part:

Part 1: The sociological notion of “balance”

Zachary’s graph by the numbers

The explanation

The correct interpretation of the triad counts in Zachary’s graph

Part 2: Preferential attachment models and power laws

The precise model of Bollobás et al

Their theorem

The good, the bad and the ugly

Part 3: Opinion dynamics

▶ First part:

The friend of my friend is my friend

▶ Second part:

The enemy of my enemy is my friend

Part 1: The sociological notion of “balance”

Zachary’s graph by the numbers

The explanation

The correct interpretation of the triad counts in Zachary’s graph

Part 2: Preferential attachment models and power laws

The precise model of Bollobás et al

Their theorem

The good, the bad and the ugly

Part 3: Opinion dynamics

▶ First part:

The friend of my friend is my friend

▶ Second part:

The enemy of my enemy is my friend

The enemy of my friend is my enemy

Part 1: The sociological notion of “balance”

Zachary’s graph by the numbers

The explanation

The correct interpretation of the triad counts in Zachary’s graph

Part 2: Preferential attachment models and power laws

The precise model of Bollobás et al

Their theorem

The good, the bad and the ugly

Part 3: Opinion dynamics

▶ First part:

The friend of my friend is my friend

▶ Second part:

The enemy of my enemy is my friend

The enemy of my friend is my enemy

The friend of my enemy is my enemy

Part 1: The sociological notion of “balance”

Zachary’s graph by the numbers

The explanation

The correct interpretation of the triad counts in Zachary’s graph

Part 2: Preferential attachment models and power laws

The precise model of Bollobás et al

Their theorem

The good, the bad and the ugly

Part 3: Opinion dynamics

▶ First part:

The friend of my friend is my friend

▶ Second part:

The enemy of my enemy is my friend

The enemy of my friend is my enemy

The friend of my enemy is my enemy

▶ The second part is more controversial as it equates absence of friendship with enmity

Part 1: The sociological notion of “balance”

Zachary’s graph by the numbers

The explanation

The correct interpretation of the triad counts in Zachary’s graph

Part 2: Preferential attachment models and power laws

The precise model of Bollobás et al

Their theorem

The good, the bad and the ugly

Part 3: Opinion dynamics

▶ First part:

The friend of my friend is my friend

▶ Second part:

The enemy of my enemy is my friend

The enemy of my friend is my enemy

The friend of my enemy is my enemy

▶ The second part is more controversial as it equates absence of friendship with enmity

▶ Nevertheless, “balance” captures the idea that connections are formed in a network primarily on the basis of affinity, rather than other factors

- Part 1: The sociological notion of “balance”
 - Zachary’s graph by the numbers
 - The explanation
- The correct interpretation of the triad counts in Zachary’s graph
- Part 2: Preferential attachment models and power laws
 - The precise model of Bollobás et al
 - Their theorem
 - The good, the bad and the ugly
- Part 3: Opinion dynamics

Definition

A **triad** in a graph G is an induced subgraph on three vertices.

Definition

A **triad** in a graph G is an induced subgraph on three vertices.

- ▶ Hence in a graph with n vertices, there are $\binom{n}{3}$ triads.

Definition

A **triad** in a graph G is an induced subgraph on three vertices.

- ▶ Hence in a graph with n vertices, there are $\binom{n}{3}$ triads.
- ▶ A triad is **balanced** if it contains either one or three edges.

Definition

A **triad** in a graph G is an induced subgraph on three vertices.

- ▶ Hence in a graph with n vertices, there are $\binom{n}{3}$ triads.
- ▶ A triad is **balanced** if it contains either one or three edges.
- ▶ Hence, in a network where relationships are formed because of affinity, there should be a greater proportion of balanced triads than in a random network of the same edge density.

Definition

A **triad** in a graph G is an induced subgraph on three vertices.

- ▶ Hence in a graph with n vertices, there are $\binom{n}{3}$ triads.
- ▶ A triad is **balanced** if it contains either one or three edges.
- ▶ Hence, in a network where relationships are formed because of affinity, there should be a greater proportion of balanced triads than in a random network of the same edge density.
- ▶ If this is not the case, then it indicates that there is a different sociological dynamic in the network.

Part 1: The sociological notion of “balance”

Zachary’s graph by the numbers

The explanation

The correct interpretation of the triad counts in Zachary’s graph

Part 2: Preferential attachment models and power laws

The precise model of Bollobás et al

Their theorem

The good, the bad and the ugly

Part 3: Opinion dynamics

- ▶ Let G be a graph with n nodes and edge density p , i.e.:

Part 1: The sociological notion of “balance”
Zachary’s graph by the numbers
The explanation
The correct interpretation of the triad counts in Zachary’s graph
Part 2: Preferential attachment models and power laws
The precise model of Bollobás et al
Their theorem
The good, the bad and the ugly
Part 3: Opinion dynamics

- ▶ Let G be a graph with n nodes and edge density p , i.e.:
$$p = [\# \text{ edges in } G] / \binom{n}{2}.$$

- ▶ Let G be a graph with n nodes and edge density p , i.e.:
$$p = [\# \text{ edges in } G] / \binom{n}{2}.$$
- ▶ If the edges were placed at random (E-R model), then the expected numbers of i -edge triads, for $i = 0, 1, 2, 3$, would be

- ▶ Let G be a graph with n nodes and edge density p , i.e.:
 $p = [\# \text{ edges in } G] / \binom{n}{2}$.
- ▶ If the edges were placed at random (E-R model), then the expected numbers of i -edge triads, for $i = 0, 1, 2, 3$, would be

$$\mathcal{E}_0 = \binom{n}{3} (1 - p)^3,$$

- ▶ Let G be a graph with n nodes and edge density p , i.e.:
 $p = [\# \text{ edges in } G] / \binom{n}{2}$.
- ▶ If the edges were placed at random (E-R model), then the expected numbers of i -edge triads, for $i = 0, 1, 2, 3$, would be

$$\mathcal{E}_0 = \binom{n}{3} (1-p)^3, \quad \mathcal{E}_1 = \binom{n}{3} 3p(1-p)^2,$$

- ▶ Let G be a graph with n nodes and edge density p , i.e.:
 $p = [\# \text{ edges in } G] / \binom{n}{2}$.
- ▶ If the edges were placed at random (E-R model), then the expected numbers of i -edge triads, for $i = 0, 1, 2, 3$, would be

$$\begin{aligned}\mathcal{E}_0 &= \binom{n}{3} (1-p)^3, & \mathcal{E}_1 &= \binom{n}{3} 3p(1-p)^2, \\ \mathcal{E}_2 &= \binom{n}{3} 3p^2(1-p),\end{aligned}$$

- ▶ Let G be a graph with n nodes and edge density p , i.e.:
 $p = [\# \text{ edges in } G] / \binom{n}{2}$.
- ▶ If the edges were placed at random (E-R model), then the expected numbers of i -edge triads, for $i = 0, 1, 2, 3$, would be

$$\begin{aligned}\mathcal{E}_0 &= \binom{n}{3} (1-p)^3, & \mathcal{E}_1 &= \binom{n}{3} 3p(1-p)^2, \\ \mathcal{E}_2 &= \binom{n}{3} 3p^2(1-p), & \mathcal{E}_3 &= \binom{n}{3} p^3.\end{aligned}$$

- ▶ Let G be a graph with n nodes and edge density p , i.e.:
$$p = [\# \text{ edges in } G] / \binom{n}{2}.$$
- ▶ If the edges were placed at random (E-R model), then the expected numbers of i -edge triads, for $i = 0, 1, 2, 3$, would be

$$\begin{aligned}\mathcal{E}_0 &= \binom{n}{3} (1-p)^3, & \mathcal{E}_1 &= \binom{n}{3} 3p(1-p)^2, \\ \mathcal{E}_2 &= \binom{n}{3} 3p^2(1-p), & \mathcal{E}_3 &= \binom{n}{3} p^3.\end{aligned}$$

- ▶ Now take an actual network and let \mathcal{N}_i , $i = 0, 1, 2, 3$, be the actual numbers of i -edge triads.

- ▶ Let G be a graph with n nodes and edge density p , i.e.:
 $p = [\# \text{ edges in } G] / \binom{n}{2}$.
- ▶ If the edges were placed at random (E-R model), then the expected numbers of i -edge triads, for $i = 0, 1, 2, 3$, would be

$$\begin{aligned} \mathcal{E}_0 &= \binom{n}{3} (1-p)^3, & \mathcal{E}_1 &= \binom{n}{3} 3p(1-p)^2, \\ \mathcal{E}_2 &= \binom{n}{3} 3p^2(1-p), & \mathcal{E}_3 &= \binom{n}{3} p^3. \end{aligned}$$

- ▶ Now take an actual network and let \mathcal{N}_i , $i = 0, 1, 2, 3$, be the actual numbers of i -edge triads. In a “balanced network” we expect to find

$$\mathcal{N}_0 < \mathcal{E}_0, \quad \mathcal{N}_1 > \mathcal{E}_1, \quad \mathcal{N}_2 < \mathcal{E}_2, \quad \mathcal{N}_3 > \mathcal{E}_3.$$

Part 1: The sociological notion of “balance”

Zachary’s graph by the numbers

The explanation

The correct interpretation of the triad counts in Zachary’s graph

Part 2: Preferential attachment models and power laws

The precise model of Bollobás et al

Their theorem

The good, the bad and the ugly

Part 3: Opinion dynamics

Kadushin’s two key assertions are the following:

- Part 1: The sociological notion of “balance”
 - Zachary’s graph by the numbers
 - The explanation
- The correct interpretation of the triad counts in Zachary’s graph
- Part 2: Preferential attachment models and power laws
 - The precise model of Bollobás et al
 - Their theorem
 - The good, the bad and the ugly
- Part 3: Opinion dynamics

Kadushin’s two key assertions are the following:

Assertion 1: “There are 1,575 symmetric dyads in the network (triad type 3-102 in chapter 2, figure 2) ... The number of dyads was much greater than would have been found by chance”.

Kadushin’s two key assertions are the following:

Assertion 1: “There are 1,575 symmetric dyads in the network (triad type 3-102 in chapter 2, figure 2) ... The number of dyads was much greater than would have been found by chance”.

Assertion 2: “There are 45 (symmetric) triads in the entire network (triad type 16-300 in chapter 2, figure 2), also far more than expected by chance”.

Part 1: The sociological notion of “balance”

Zachary’s graph by the numbers

The explanation

The correct interpretation of the triad counts in Zachary’s graph

Part 2: Preferential attachment models and power laws

The precise model of Bollobás et al

Their theorem

The good, the bad and the ugly

Part 3: Opinion dynamics

- ▶ There are 34 nodes and 78 edges in the graph, hence $p = 78 / \binom{34}{2} = 78 / 561 \approx 0.139$.

- ▶ There are 34 nodes and 78 edges in the graph, hence $p = 78 / \binom{34}{2} = 78 / 561 \approx 0.139$.
- ▶ This yields

$$\mathcal{E}_0 \approx 3819, \quad \mathcal{E}_1 \approx 1850, \quad \mathcal{E}_2 \approx 299, \quad \mathcal{E}_3 \approx 16.$$

- ▶ There are 34 nodes and 78 edges in the graph, hence $p = 78/\binom{34}{2} = 78/561 \approx 0.139$.
- ▶ This yields

$$\mathcal{E}_0 \approx 3819, \quad \mathcal{E}_1 \approx 1850, \quad \mathcal{E}_2 \approx 299, \quad \mathcal{E}_3 \approx 16.$$

- ▶ The actual numbers for this graph are

$$\mathcal{N}_0 = 3971, \quad \mathcal{N}_1 = 1575, \quad \mathcal{N}_2 = 393, \quad \mathcal{N}_3 = 45.$$

- ▶ There are 34 nodes and 78 edges in the graph, hence $p = 78/\binom{34}{2} = 78/561 \approx 0.139$.

- ▶ This yields

$$\mathcal{E}_0 \approx 3819, \quad \mathcal{E}_1 \approx 1850, \quad \mathcal{E}_2 \approx 299, \quad \mathcal{E}_3 \approx 16.$$

- ▶ The actual numbers for this graph are

$$\mathcal{N}_0 = 3971, \quad \mathcal{N}_1 = 1575, \quad \mathcal{N}_2 = 393, \quad \mathcal{N}_3 = 45.$$

- ▶ So this graph is quite unbalanced !

- ▶ There are 34 nodes and 78 edges in the graph, hence $p = 78 / \binom{34}{2} = 78/561 \approx 0.139$.
- ▶ This yields

$$\mathcal{E}_0 \approx 3819, \quad \mathcal{E}_1 \approx 1850, \quad \mathcal{E}_2 \approx 299, \quad \mathcal{E}_3 \approx 16.$$

- ▶ The actual numbers for this graph are

$$\mathcal{N}_0 = 3971, \quad \mathcal{N}_1 = 1575, \quad \mathcal{N}_2 = 393, \quad \mathcal{N}_3 = 45.$$

- ▶ So this graph is quite unbalanced ! Where did Kadushin’s first assertion come from ?

- ▶ There are 34 nodes and 78 edges in the graph, hence $p = 78/\binom{34}{2} = 78/561 \approx 0.139$.
- ▶ This yields

$$\mathcal{E}_0 \approx 3819, \quad \mathcal{E}_1 \approx 1850, \quad \mathcal{E}_2 \approx 299, \quad \mathcal{E}_3 \approx 16.$$

- ▶ The actual numbers for this graph are

$$\mathcal{N}_0 = 3971, \quad \mathcal{N}_1 = 1575, \quad \mathcal{N}_2 = 393, \quad \mathcal{N}_3 = 45.$$

- ▶ So this graph is quite unbalanced ! Where did Kadushin's first assertion come from ? After consultation with him, he provided us with his numbers, obtained using Pajek:

$$\mathcal{E}_{1,\kappa} \approx 190.68... \quad \mathcal{E}_{3,\kappa} \approx 0.04...$$

- ▶ There are 34 nodes and 78 edges in the graph, hence $p = 78/\binom{34}{2} = 78/561 \approx 0.139$.

- ▶ This yields

$$\mathcal{E}_0 \approx 3819, \quad \mathcal{E}_1 \approx 1850, \quad \mathcal{E}_2 \approx 299, \quad \mathcal{E}_3 \approx 16.$$

- ▶ The actual numbers for this graph are

$$\mathcal{N}_0 = 3971, \quad \mathcal{N}_1 = 1575, \quad \mathcal{N}_2 = 393, \quad \mathcal{N}_3 = 45.$$

- ▶ So this graph is quite unbalanced ! Where did Kadushin's first assertion come from ? After consultation with him, he provided us with his numbers, obtained using Pajek:

$$\mathcal{E}_{1,\kappa} \approx 190.68... \quad \mathcal{E}_{3,\kappa} \approx 0.04...$$

- ▶ What ???????

Part 1: The sociological notion of “balance”
Zachary’s graph by the numbers
The explanation
The correct interpretation of the triad counts in Zachary’s graph
Part 2: Preferential attachment models and power laws
The precise model of Bollobás et al
Their theorem
The good, the bad and the ugly
Part 3: Opinion dynamics

- ▶ The key to understanding his mistake is found in the sentence “The overall density is 0.139 with 156 connections out of a total of 1,112 possible connections”.

- ▶ The key to understanding his mistake is found in the sentence “The overall density is 0.139 with 156 connections out of a total of 1,112 possible connections”.
- ▶ Note $156 = 2 \times 78$. Leaving aside that $2 \times 561 = 1,222$, not 1,112, why is Kadushin counting every edge twice ?

- ▶ The key to understanding his mistake is found in the sentence “The overall density is 0.139 with 156 connections out of a total of 1,112 possible connections”.
- ▶ Note $156 = 2 \times 78$. Leaving aside that $2 \times 561 = 1,222$, not 1,112, why is Kadushin counting every edge twice ?
- ▶ Because he is comparing the network with random **directed** networks !

- ▶ The key to understanding his mistake is found in the sentence “The overall density is 0.139 with 156 connections out of a total of 1,112 possible connections”.
- ▶ Note $156 = 2 \times 78$. Leaving aside that $2 \times 561 = 1,222$, not 1,112, why is Kadushin counting every edge twice ?
- ▶ Because he is comparing the network with random **directed** networks ! Thus,

$$\mathcal{E}_{1,\kappa} = \binom{n}{3} 3p^2(1-p)^4 = 190.68\dots \quad \mathcal{E}_{3,\kappa} = \binom{n}{3} p^6 = 0.04\dots$$

- ▶ The key to understanding his mistake is found in the sentence “The overall density is 0.139 with 156 connections out of a total of 1,112 possible connections”.
- ▶ Note $156 = 2 \times 78$. Leaving aside that $2 \times 561 = 1,222$, not 1,112, why is Kadushin counting every edge twice ?
- ▶ Because he is comparing the network with random **directed** networks ! Thus,

$$\mathcal{E}_{1,\kappa} = \binom{n}{3} 3p^2(1-p)^4 = 190.68\dots \quad \mathcal{E}_{3,\kappa} = \binom{n}{3} p^6 = 0.04\dots$$

- ▶ You cannot assume relationships are symmetric when making the graph and then compare it with random graphs in which this assumption is dropped !

Part 1: The sociological notion of “balance”

Zachary’s graph by the numbers

The explanation

The correct interpretation of the triad counts in Zachary’s graph

Part 2: Preferential attachment models and power laws

The precise model of Bollobás et al

Their theorem

The good, the bad and the ugly

Part 3: Opinion dynamics

- ▶ One could simply conclude that Zachary was wrong to assume friendships were mutual when making his graph.

Part 1: The sociological notion of “balance”

Zachary’s graph by the numbers

The explanation

The correct interpretation of the triad counts in Zachary’s graph

Part 2: Preferential attachment models and power laws

The precise model of Bollobás et al

Their theorem

The good, the bad and the ugly

Part 3: Opinion dynamics

- ▶ One could simply conclude that Zachary was wrong to assume friendships were mutual when making his graph.
- ▶ So either he was aware of this problem, but made his graph undirected anyway, or he was unable to pick up such “tensions” between apparent friends in his observations.

Part 1: The sociological notion of “balance”

Zachary’s graph by the numbers

The explanation

The correct interpretation of the triad counts in Zachary’s graph

Part 2: Preferential attachment models and power laws

The precise model of Bollobás et al

Their theorem

The good, the bad and the ugly

Part 3: Opinion dynamics

- ▶ One could simply conclude that Zachary was wrong to assume friendships were mutual when making his graph.
- ▶ So either he was aware of this problem, but made his graph undirected anyway, or he was unable to pick up such “tensions” between apparent friends in his observations.
- ▶ Let’s give him the benefit of the doubt and assume the latter.

The correct interpretation of the triad counts in Zachary’s graph

- ▶ One could simply conclude that Zachary was wrong to assume friendships were mutual when making his graph.
- ▶ So either he was aware of this problem, but made his graph undirected anyway, or he was unable to pick up such “tensions” between apparent friends in his observations.
- ▶ Let’s give him the benefit of the doubt and assume the latter.
- ▶ The really salient feature of the graph is the overrepresentation of 2-edge triads: $\mathcal{N}_2 = 393 > 299 = \mathcal{E}_2$.

The correct interpretation of the triad counts in Zachary’s graph

- ▶ One could simply conclude that Zachary was wrong to assume friendships were mutual when making his graph.
- ▶ So either he was aware of this problem, but made his graph undirected anyway, or he was unable to pick up such “tensions” between apparent friends in his observations.
- ▶ Let’s give him the benefit of the doubt and assume the latter.
- ▶ The really salient feature of the graph is the overrepresentation of 2-edge triads: $\mathcal{N}_2 = 393 > 299 = \mathcal{E}_2$.
- ▶ This is indicative of **stardom** or **hierarchy**.

The correct interpretation of the triad counts in Zachary’s graph

- ▶ One could simply conclude that Zachary was wrong to assume friendships were mutual when making his graph.
- ▶ So either he was aware of this problem, but made his graph undirected anyway, or he was unable to pick up such “tensions” between apparent friends in his observations.
- ▶ Let’s give him the benefit of the doubt and assume the latter.
- ▶ The really salient feature of the graph is the overrepresentation of 2-edge triads: $\mathcal{N}_2 = 393 > 299 = \mathcal{E}_2$.
- ▶ This is indicative of **stardom** or **hierarchy**.
- ▶ Ordinary club members were driven, especially after the schism, to form relationships with high-ranking members, rather than with one another.

The correct interpretation of the triad counts in Zachary’s graph

- ▶ One could simply conclude that Zachary was wrong to assume friendships were mutual when making his graph.
- ▶ So either he was aware of this problem, but made his graph undirected anyway, or he was unable to pick up such “tensions” between apparent friends in his observations.

HOT EXAMPLE: World Wide Web (WWW), which people could see growing before their eyes at the time.

FOCUS ON: The so-called “scale-free” property, which is most popularly expressed by the idea that the distribution of vertex degrees follows a power law, i.e.:

- Part 1: The sociological notion of “balance”
 - Zachary’s graph by the numbers
 - The explanation
- The correct interpretation of the triad counts in Zachary’s graph
- Part 2: Preferential attachment models and power laws**
 - The precise model of Bollobás et al
 - Their theorem
 - The good, the bad and the ugly
- Part 3: Opinion dynamics

Let $P(d)$ be the proportion of vertices that have degree d . Then

$$P(d) \propto d^{-\gamma},$$

for some fixed positive constant γ .

Let $P(d)$ be the proportion of vertices that have degree d . Then

$$P(d) \propto d^{-\gamma},$$

for some fixed positive constant γ .

This is quite different from a Poisson distribution

$$P(d) \approx e^{-\lambda} \frac{\lambda^d}{d!},$$

where $\lambda =$ average degree. For $G(n,p)$, $\lambda = (n - 1)p$.

Let $P(d)$ be the proportion of vertices that have degree d . Then

$$P(d) \propto d^{-\gamma},$$

for some fixed positive constant γ .

This is quite different from a Poisson distribution

$$P(d) \approx e^{-\lambda} \frac{\lambda^d}{d!},$$

where $\lambda =$ average degree. For $G(n,p)$, $\lambda = (n-1)p$.

Barabási-Albert proposed a specific growth model and claimed their simulations indicated convergence to a power law distribution with $\gamma = 2.9 \pm 0.1$.

- ▶ Fix a positive integer m .

To even define a preferential attachment growth model rigorously is a non-trivial exercise. The text in B-A did not make sense (I don’t know about their simulations) and the first step was to clean it up.

- ▶ Fix a positive integer m .
- ▶ We define a sequence of graphs G_m^1, G_m^2, \dots inductively.

To even define a preferential attachment growth model rigorously is a non-trivial exercise. The text in B-A did not make sense (I don’t know about their simulations) and the first step was to clean it up.

- ▶ Fix a positive integer m .
- ▶ We define a sequence of graphs G_m^1, G_m^2, \dots inductively.
- ▶ G_1^1 consists of a single vertex with a loop.

To even define a preferential attachment growth model rigorously is a non-trivial exercise. The text in B-A did not make sense (I don’t know about their simulations) and the first step was to clean it up.

- ▶ Fix a positive integer m .
- ▶ We define a sequence of graphs G_m^1, G_m^2, \dots inductively.
- ▶ G_1^1 consists of a single vertex with a loop.
- ▶ At step t we add one new vertex v_t and m new incident edges.

$$\mathbb{P}(v_j = v_s) = \begin{cases} \frac{d_{G_{\text{now}}}^{\text{tot}}(v_s)}{2E+1}, & \text{if } s < t, \\ \frac{1}{2E+1}, & \text{if } s = t. \end{cases} \quad (1)$$

$$\mathbb{P}(v_i = v_s) = \begin{cases} \frac{d_{\text{Gnow}}^{\text{tot}}(v_s)}{2E+1}, & \text{if } s < t, \\ \frac{1}{2E+1}, & \text{if } s = t. \end{cases} \quad (1)$$

- ▶ **Obs!** The model allows for loops and multiple edges.

$$\mathbb{P}(v_i = v_s) = \begin{cases} \frac{d_{\text{Gnow}}^{\text{tot}}(v_s)}{2E+1}, & \text{if } s < t, \\ \frac{1}{2E+1}, & \text{if } s = t. \end{cases} \quad (1)$$

- ▶ **Obs!** The model allows for loops and multiple edges.
- ▶ d^{tot} denotes total degree, which means loops contribute two, whereas an edge between v_t and v_s , where $t > s$, contributes one to the *indegree* of v_s and one to the *outdegree* of v_t .

$$\mathbb{P}(v_i = v_s) = \begin{cases} \frac{d_{\text{Gnow}}^{\text{tot}}(v_s)}{2E+1}, & \text{if } s < t, \\ \frac{1}{2E+1}, & \text{if } s = t. \end{cases} \quad (1)$$

- ▶ **Obs!** The model allows for loops and multiple edges.
- ▶ d^{tot} denotes total degree, which means loops contribute two, whereas an edge between v_t and v_s , where $t > s$, contributes one to the *indegree* of v_s and one to the *outdegree* of v_t .
- ▶ E is the current number of edges. Thus (1) says that vertices which currently have higher degree are more likely to get new connections \Rightarrow **preferential attachment**.

$$\alpha_{m,d} := \frac{2m(m+1)}{(d+m)(d+m+1)(d+m+2)}.$$

Let $\epsilon > 0$. Then with probability 1, as $n \rightarrow \infty$ we have

$$(1 - \epsilon)\alpha_{m,d} \leq \frac{\mathcal{N}_m^n(d)}{n} \leq (1 + \epsilon)\alpha_{m,d}$$

for every d in the range $0 \leq d \leq n^{1/15}$.

Part 1: The sociological notion of “balance”

Zachary’s graph by the numbers

The explanation

The correct interpretation of the triad counts in Zachary’s graph

Part 2: Preferential attachment models and power laws

The precise model of Bollobás et al

Their theorem

The good, the bad and the ugly

Part 3: Opinion dynamics

THE GOOD:

Part 1: The sociological notion of “balance”

Zachary’s graph by the numbers

The explanation

The correct interpretation of the triad counts in Zachary’s graph

Part 2: Preferential attachment models and power laws

The precise model of Bollobás et al

Their theorem

The good, the bad and the ugly

Part 3: Opinion dynamics

THE GOOD:

We have some mathematically rigorous support for the hypothesis that preferential attachment is a crucial mechanism in the growth of real networks.

Part 1: The sociological notion of “balance”

Zachary’s graph by the numbers

The explanation

The correct interpretation of the triad counts in Zachary’s graph

Part 2: Preferential attachment models and power laws

The precise model of Bollobás et al

Their theorem

The good, the bad and the ugly

Part 3: Opinion dynamics

THE GOOD:

We have some mathematically rigorous support for the hypothesis that preferential attachment is a crucial mechanism in the growth of real networks.

THE BAD:

THE GOOD:

We have some mathematically rigorous support for the hypothesis that preferential attachment is a crucial mechanism in the growth of real networks.

THE BAD:

The theorem predicts a specific power $\gamma = 3$.

Part 1: The sociological notion of “balance”

Zachary’s graph by the numbers

The explanation

The correct interpretation of the triad counts in Zachary’s graph

Part 2: Preferential attachment models and power laws

The precise model of Bollobás et al

Their theorem

Part 3: Opinion dynamics

THE GOOD:

We have some mathematically rigorous support for the hypothesis that preferential attachment is a crucial mechanism in the growth of real networks.

THE BAD:

The theorem predicts a specific power $\gamma = 3$. Name your favorite positive real number γ and you can probably find a paper in the literature showing data following a power law $P(d) \propto d^{-\gamma}$.

THE GOOD:

We have some mathematically rigorous support for the hypothesis that preferential attachment is a crucial mechanism in the growth of real networks.

THE BAD:

The theorem predicts a specific power $\gamma = 3$. Name your favorite positive real number γ and you can probably find a paper in the literature showing data following a power law $P(d) \propto d^{-\gamma}$.

THE UGLY:

THE GOOD:

We have some mathematically rigorous support for the hypothesis that preferential attachment is a crucial mechanism in the growth of real networks.

THE BAD:

The theorem predicts a specific power $\gamma = 3$. Name your favorite positive real number γ and you can probably find a paper in the literature showing data following a power law $P(d) \propto d^{-\gamma}$.

THE UGLY:

The bound of $d \leq n^{1/15}$ in the theorem means that it effectively says nothing whatsoever about any real network !!
